"existing" and formed or laid out as for building at the time of the Act of 1878; (3) that the appellant had constructed the southernmost shop so that the boundary of the "forecourt" was at less than the prescribed distance from the centre of the road of Church-lane. And the magistrate accordingly convicted the defendant, who appealed. Mr. R. Cunningham Glen argued for the appellant, and contended—(1) That there was no evidence that the fence was the external fence or boundary, and, indeed, he urged that the evidence rather showed the contrary. On this point he cited "*Meadows v. Taylor*," and "*Hobbs v. Dance*." (2) that Church-lane was an "existing street" at the time of the passing of the Act of 1878. That Act and the Act of 1855 was, he urged, to be read as one Act. And the word "existing" would be unnecessary, unless it meant something different from "formed" or "laid out for building"; (3) that there was no evidence on which the magistrate could find Church-lane not "an existing street" within the Act. Mr. Daldy argued in support of the conviction, controverting the argument for the appellant on these points. In the Public Health Act, 1875, "street" includes any highway not being a turnpike road. He cited "*the Mayor of Portsmouth v. Smith*." This was not a "street" within the exception. After a very long argument on Saturday and Monday, the Court of Queen's Bench came to the conclusion that the order was wrong. Mr. Baron Pollock, in giving judgment, said the contention on the part of the County Council was that this Church-lane was not an "existing street" at the time of the passing of the Act of 1878. The magistrate had, no doubt, found that it was not so, but had also found facts from which the Court could see that it was so, and, therefore, the order was wrong. Mr. Justice Hawkins entirely agreed. Order, therefore, set aside.

ARCHITECTS AND CLIENT IN LITIGATION.—**DENNIS v. CROCKER.**—The adjourned hearing of this claim for five guineas took place at Bodmin County-court on Friday. The plaintiffs, father and son, the former a retired builder and the latter an architect of Birmingham, claimed from defendant, a store-keeper of Bodmin Asylum, £5 5s., charged for the preparation of plans for the erection of buildings. Tenders had shown that the four houses it was contemplated erecting on defendant's property would cost more than it was intended to spend, and a suggestion made that five houses might be built at a reduced cost was agreed on with a limit to price, and the elder plaintiff superintended the erections made from further plans by the younger. When plaintiffs presented their bill an item for £5 5s. for the first set of plans was not paid; all the rest was. There was a counter-claim for £50 for losses and expenses alleged by defendant to have been sustained through negligent and unskilful work. The defence was that the younger plaintiff agreed not to charge for the first plans. The counter-claim defence was that the plans had to be departed from on account of a hedge, which was stated to be included in the property, having been excluded. Judge Granger, in summing up, said with regard to the claim of £5 5s. for the first set of plans, he could not put any other interpretation on it than that if the second set of plans came to about the estimate Mr. Crocker was willing to lay out, Dennis was to get the £5 5s., and he should therefore allow it with costs. With regard to the drainage of the premises, it seemed a most remarkable thing that in a town the size of Bodmin absolutely no by-law existed, and no check was put by the sanitary authority on what people did or how they connected with the main drain. As there had been no evidence on the part of Mr. Crocker to prove the drain had not been properly laid, he had no alternative but to decide that it had. On the counter-claim, although the matter was pointed out to Mr. Dennis, yet Mr. Crocker condoned the matter by paying Dennis his full claim on this account. He therefore gave judgment for Dennis with costs, and dismissed the counterclaim.

DRAINS AND SCARLET FEVER.—**FOSTER v. FARQUHAR.**—The trial of an action brought by Mr. R. C. Foster against the executors of the late Sir E. H. Scott to recover damages for the breach of an agreement to put the drains of a house in repair, concluded on Monday. After the plaintiff had taken possession of a house in Sundridge-avenue, Bromley, Kent, his family were seized with scarlet fever, and the question in dispute was whether the illness was attributable to sewer-gas, which found its way into the house, or to the prevalence of fever in the district at the time. Expert evidence was given on both sides as to the condition of the drains.—The jury gave a verdict for the plaintiff for twelve guineas, and Mr. Justice Cave reserved the question of costs.

The Earl of Rosebery will unveil a memorial to the late Sir John Macdonald, Premier of Canada, in St. Paul's Cathedral on Wednesday next. The memorial, which consists of a white marble bust in heroic size, is the work of Mr. George Wade.

WATER SUPPLY AND SANITARY MATTERS.

SALE, MANCHESTER.—The Local Government Board has now approved of the scheme prepared by Mr. M'Beath, surveyor to the board, for the purification of the sewage of the township, and given its sanction for the borrowing of £19,500 for the purchase of the land and the execution of the works. The plans were submitted to the Local Government Board in 1890 in order to meet the requirements of the Rivers Pollution Act as pointed out in a circular issued by the Manchester Ship Canal Company. The system adopted for the purification of the sewage is one of precipitation and filtration. The site of the works is near the Bridgewater Canal, and will cover an area of 5½ acres; but the total area to be acquired for sewage and other purposes is 15½ acres. The work will be commenced without delay.

CHIPS.

The foundation-stones of a new habitation which is being built for the Shipley corps of the Salvation Army were laid on Saturday last. The site has frontages to Commercial-street and Rhodes's-place. The plans have been prepared at headquarters, and Messrs. Rhodes Brothers have taken the contracts at about £2,000. The large central hall of the new barracks is intended to accommodate about 800 persons.

The annual luncheon of the Royal Scottish Society of Water-Colour Painters took place on Friday in the Fine Art Institute, Glasgow, where the exhibition of the society is being held. Mr. Francis Powell, president of the society, occupied the chair, and about a hundred sat down.

The name of Mr. Henry Roberts, of Latchford, near Warrington, builders' merchant, has been added to the commission of the peace for Warrington.

New board schools in Victoria-road, Middlesbrough, have just been completed, and will be opened in a few days. Mr. Bottomley, of that town, was the architect.

A large new clock has just been erected on Ridgmont Church Tower, Bedfordshire, which will doubtless prove a great boon to the inhabitants. The hours are struck upon a large bell, and there are two very distinct dials, each 4ft. 6in. diameter, facing north and west. All the latest improvements have been incorporated in the clock, which has been made by John Smith and Sons, Midland Clock Works, Derby.

At Farncombe—one of the districts of the greatly enlarged borough of Godalming—was opened last week a church room for the encouragement of the "social activities" of the parish. As one of these is the teaching of cooking, a special room is provided with range, sink, &c., and this serves also by a little arrangement as a retiring or committee room attached to the larger one, which will accommodate about 150 people. The architect is Mr. Charles Forster Hayward, F.S.A., and the builders Messrs. Mitchell Bros., of Stratford. Altogether, it promises to be a great success, having been opened by the Bishop of Winchester with great éclat.

About a century ago the celebrated Dr. Crotch, Regius Professor at Cambridge, was invited to compose chimes for the new clock erected at that time for the Great St. Mary's Church, Cambridge, and he adapted the chimes from Handel's air, "I know that my Redeemer liveth," and which are now heard in every part of the kingdom. The old clock having got considerably worn, the council decided to ask a few well known firms to compete for a new clock made on modern principles, but to have the original chimes inserted and to strike them upon the original bells. Messrs. Potts and Sons, of Leeds, were intrusted with the order, and have this week completed the work. The old clock has been removed and fixed in the museum.

Messrs. Burt and Potts have just made, fixed, and glazed a very large number of their casements for the Queen Regent of Spain, for her new summer palace at San Sebastian, and are now making the casements for the lodges at the same place. They have also just completed some very large folding casements for the Prince of Wales, for Sandringham Hall; and these they have also fixed and glazed, as also those for the Adelphi Bank, Liverpool. They have also completed within the last few months, or have still in hand, casements for the following:—The Prudential Assurance Company, Leeds, under Messrs. A. Waterhouse and Son, and for a very large house at Maidstone under the same architects; the Grocers' Hall, Princes-street, E.C.; the extension of the School Board offices, Thames Embankment; Messrs. Kelly and Co.'s new offices, 182-4, High Holborn; houses for his Grace the late Duke of Sutherland, at Windsor; Friar Park, Henley (a very large order); the Bury, King's Walden (also a very large order); new premises, 1 to 4, Duke-street, W.; new buildings, Carlos-place and Mount-street, W., &c.

Our Office Table.

THE forty-fifth anniversary dinner in aid of the funds of the Builders' Benevolent Institution, was held on the 3rd inst., at Carpenters' Hall, London-wall. Mr. Joseph Randall, the president of the institution, occupied the chair. The chairman, in proposing the toast of the evening, "Success to the Builders' Benevolent Institution," reminded his hearers that the charity was founded in 1847. At present 54 pensioners were in receipt of relief—viz., 19 men and 35 women, whose average age was 74 years. To maintain so many pensioners, liberal donations were necessary, especially as the annual subscriptions had somewhat fallen off. Why the female pensioners were so numerous as compared with the men, was that the widows of pensioners had been admitted on the death of their husbands. The income last year from all sources was £2,056, and the expenditure £2,070. The institution had about 700 donors and subscribers, a number which could, and should, be largely increased. Many of the pensioners had once been in good and even affluent circumstances; but, from causes which they had been unable to control, had found themselves reduced, and with no other resources left them but the benefits arising from this institution. It would, therefore, be a great hardship to curtail the annuities of present pensioners for want of funds, or to postpone the election of the five approved candidates, who were in straitened circumstances, and eagerly looking forward to early election. Mr. Plucknett replied on behalf of the institution, and thanked the president for his anxiety to help the charity. In the course of the evening subscriptions and donations to the amount of £492 were announced, of which sum £400 appeared in the president's list.

The London School Board again considered, at their last meeting, the proposal brought forward by the Works Committee, to the effect that the preparation of the plans of the new school to be erected in Priory-street, Bromley, should be placed in the hands of an outside architect to be selected by competition, and that the committee should prepare and submit for the acceptance of the Board the conditions of the competition. Mr. Lyulph Stanley proposed an amendment, referring the matter back to the committee, instructing them to submit further particulars, and asking whether it was proposed to pay an outside architect the usual professional commission of 5 per cent. The amendment, after a long discussion, was agreed to.

At Messrs. Minton's works at Stoke-on-Trent, on Saturday, a presentation was made to M. J. F. Léon Arnoux, on the occasion of his retiring from the post of art director to the firm, which he has held for upwards of 40 years. At the invitation of his friends, M. Arnoux selected specimens of three kinds of ware, which are almost exclusively manufactured by Minton's—viz., Henri-Deux candlestick and ewer; a Pembroke ewer, inkstand, and plate, in pâte-sur-pâte; and a pair of plaques, Barbetine. The pâte-sur-pâte specimens are the work of M. Solon, and the plaques have been decorated by M. Boule-mier with an arrangement after Watteau. The monetary value of the ware is about £100. At the gathering on Saturday afternoon, Alderman G. Leasons, one of the directors of the firm, presided, and the specimens of ware, together with an illuminated album containing an address, from employés who have seen upwards of 50 years' service with the firm, were presented to Mr. Arnoux.

"The Cost of Electric Light Supply" was selected by Dr. John Hopkinson, F.R.S., as the subject for his inaugural address as president of the Junior Engineering Society. In the course of this paper, read at the Westminster Palace Hotel on Friday evening, Dr. Hopkinson put the conjectural case of a station capable of supplying 40,000 16-candle lamps at one time, with mains and spare machinery enough to insure that the supply shall not fail. This station must always be ready to supply the 40,000 lights at half an hour's notice, day or night; but the lights were hardly ever actually required. Next they must suppose that the 40,000 lights were steadily and continuously supplied day and night. These were the two extreme cases possible. In the former the load factor was nil; in the latter it was 100 per cent. If the charge was by meter at 8d. per unit in the former case the revenue

would be nil; in the latter it would be £730,000 a year. To provide the maximum of 40,000 lamps they would need to deliver 2,500 units per hour, and the capital outlay would amount to £145,000. The cost of merely being ready to supply 2,500 units per hour at any moment would be £28,010, and the cost of actually supplying that quantity per hour would be £59,250. A Board of Trade unit was equivalent to 125c.ft. of gas. To be ready to supply a customer with electricity at any moment would cost those giving the supply not much less than £11 per annum for every unit per hour, and afterwards to give the supply would not cost very much more than 1-3d. per unit.

At the last meeting of the South Hants and Isle of Wight District Council of the Worshipful Company of Plumbers, held the other day at the Municipal-buildings, Southampton, it was resolved, on the motion of Dr. Mumby (medical officer of health), seconded by Mr. Blizard (master plumber), that the sum of two guineas be offered in prizes to the students attending the plumbing classes at the Hartley Institution. The subject of forming a local committee at Portsmouth, to act in co-operation with the council, was discussed, members from that town reporting the steps already taken in the matter. The council ultimately decided to adjourn the further consideration of the matter until the next meeting. It was resolved to hold an examination of candidates for registration at Bournemouth on the 19th inst., and the opinion was expressed that there would be a good attendance thereat.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Surveyors' Institution. Opening Address by the President, C. J. Shoppee. 8 p.m.

TUESDAY.—The Society of Architects. Opening Address by the President, Robert Walker, of Cork. 3 p.m. Annual Dinner at Holborn Restaurant. 7.30 p.m.

Institution of Civil Engineers. Papers on Graving Docks at Halifax, N.S.; Cockatoo Island, N.S.W.; Belfast and Newport, Mon. by the Hon. R. C. Parsons, E. W. Young, W. Radfern Kelly, and Robert Pickwell. 8 p.m.

WEDNESDAY.—Society of Arts. Opening Address of the 139th Session, by Sir R. E. Webster, Q.C., M.P., Chairman of the Council. 8 p.m.

FRIDAY.—Architectural Association. "Some Mysteries of Modern Architecture," by Paul Waterhouse, M.A. 7.30 p.m.

The Architectural Association.—November 18. The Second Ordinary General Meeting at 7.30 p.m. Paper by Paul Waterhouse, Esq., on "Some Mysteries of Modern Architecture."

ERNEST S. GALE } Hon. Secs.
F. T. W. GOLDSMITH }

Sir Frederic Leighton on Saturday evening opened the Royal Academy Students' Club at 9, Conduit-street. Afterwards he was present at a smoking concert given by the students with the aid of several well-known professionals. Mr. Alma-Tadema, R.A., presided, and was supported by Mr. Waterhouse, E.A., Mr. David Murray, A.R.A., and Mr. Seymour Lucas, A.R.A.

A new watering-place is being developed at Bouldon-on-Sea, Isle of Wight. An important stage in the enterprise was marked on Wednesday week by the driving of the first pile of the intended jetty and landing-stage. The landing-stage will be completed as quickly as possible to enable building material to be landed for the erection of numerous villas. Groynes are also to be carried out seawards, and a substantial concrete seawall is to be erected along part of the sea front of the estate, which will form an esplanade. Preparations for the commencement of these works have already been made. The arrangements are in the hands of Mr. John Fowle, architect and surveyor, of South Kensington.

The Bishop of Lichfield consecrated, on Tuesday week, the new chancel, morning chapel, organ-chamber, vestry, and sacristy which have been added to All Saints' Church, Steelhouse-lane, Wolverhampton. The work has been carried out in harmony with the style of the main portion of the edifice. The structural work was executed by Messrs. H. Willcock and Co. and the ornamental ironwork was supplied by Messrs. Hart, Peard, and Co., Birmingham, while the east window has been filled with stained glass by Messrs. Hardman, Birmingham. The interior of the church has been re-furnished, and some embroidered altar frontals, crimson velvet hangings for the sanctuary, crosses, vases, and other articles, were contributed as special gifts. The total cost of the work is £2,000. The architect was Mr. F. J. Beck, Wolverhampton.

Trade News.

WAGES MOVEMENTS.

THE CARDIFF STRIKE.—At the instance of the Bristol and other master builders' associations in the West of England and South Wales, a meeting of the council of the National Association of Master Builders was held in Birmingham last week for the purpose of considering the state of the strike at Cardiff in all the branches of the building trade, with the exception of the carpenters and joiners, who have been settled with. The following resolution was passed:—"That this association desires to place on record its appreciation of the firm stand the Cardiff Master Builders' Association are making in the protracted strike in the building trades in their town, and pledges itself to assist them by every legitimate means."

KINGSTON-ON-THAMES.—In view of the organisation of various branches of operatives employed in the building trades in the district, the master builders have formed an association which will cover a radius of five miles from Kingston Market-place. Already most of the local firms have joined the association, and one of the first acts of the association will be to prepare a schedule of prices which all the firms included in the association will pledge themselves to adhere to. At the present time there is no recognised standard rate of wage for the district.

WOOLWICH.—Forty-one joiners in the employ of Messrs. Kirk and Randall, struck work on Monday morning, and their example was followed at noon by the carpenters employed on the local jobs at the Arsenal and elsewhere, owing to the firm refusing to accede to the new rules which came into force on that morning throughout the extended "London district." The secretary of the London United Trades Committee, accompanied by Mr. C. Matkin, endeavoured to arrange an amicable settlement, but were refused an interview. The men held a meeting in the evening, and a resolution was carried unanimously claiming the full rate of 9½d. per hour, and calling upon the federated trades to assist them, and, if necessary, to block the firm throughout the district.

CHIPS.

Mr. G. F. Burr, M.S.A., architect, late of 27, Havelock-road, Hastings, having retired from practice, requests that no further trade or other circulars be sent to his old offices, as he has no use for them. We understand that Mr. Burr will still retain his membership of the Society of Architects although retiring into private life, and intends to devote his time to the management of his own estates in Worcestershire which he has lately succeeded to.

A memorial stained glass, by Mr. C. E. Kempe, of London, was unveiled at Alrewas parish church last week. It is of four lights, filled in with full-length figures of S. Augustine, the angel Gabriel, the Blessed Virgin, and St. Chad.

A water-colour drawing of Marple Locks, by Mr. S. H. Hopwood, has been purchased for the permanent gallery at Whitworth Park. Mr. Hopwood's picture is now in the autumn exhibition of the Manchester City Art Gallery.

An archaeological convention has been formed for the East Riding, with headquarters at Hull. The Rev. Dr. J. Charles Cox, F.S.A., has been elected first president and Mr. T. Tindall Wildridge honorary secretary.

New printing and publishing premises have just been built at Bury, Lancs., for the *Bury Times* from designs by Messrs. Maxwell and Tuke, of Corporation-street, Manchester. The building occupies the corner of Cross and Clerke streets, and has an octagonal turret over the entrance at the junction of the streets. The walling is of Ruabon bricks with moulded dressings. The printing shop is 72ft. by 42ft., with a wing 25ft. by 20ft. The compositors' room, on the first floor, is 55ft. by 52ft. The contractor is Mr. John Tinline, of Bury.

At the South Kensington Museum the erection is now being completed of an exact copy of a late Twelfth Century mosaic, "Christ entering Jerusalem," in the Cappella Palatina of Palermo. This is executed, not on paper, but in glass mosaic, similar to that out of which the original is put together.

At a meeting of the directors of Inverness Academy, held on Friday, it was agreed that Mr. Alexander Ross, architect, be instructed to prepare plans and specifications for a new academy, at a cost not exceeding £7,000.

The reading and magazine rooms of the free library at Clapham will be opened on Sundays from 3 to 9 p.m. from the beginning of December till the end of May.

Dear Sir,

I beg to inform you that Mr. Phipps and I have dissolved partnership, and that I have purchased from him all his share and interest in the business of Rashleigh Phipps and Dawson, and that Mr. Rashleigh Phipps has retired from the business, as from the 14th ult.

The business will be carried on as heretofore, at 53, Berners-street, by me, under the style of Roger Dawson. I shall also carry on the works for the manufacture of Electrical Fittings at Stanhope-street, Euston-road, as well as the branch establishment at Bournemouth.

I have arranged to retain the services of the same competent staff of artists and representatives, who have been hitherto employed by the late firm.

May I ask that when you require anything in Electrical Wiring or Fittings, you will give me the opportunity of quoting prices or submitting drawings?

I desire to mention that I am in no way connected with the business which is advertised as being now carried on under the name of Rashleigh Phipps and Co., at 102, Oxford-street, and that all accounts due and from the old firm will be respectively received and discharged by me.—I have the honour to be your obedient servant,

ROGER DAWSON,
53, Berners-street, W., London.
November 5, 1892.

Holloway's Ointment and Pills exercise priceless power over Lumbago, all pains of the muscles, nerves, and joints, and quickly reduce all swellings caused by accidental injuries, weakness, or hereditary taints. The intelligible instructions enveloping Holloway's medicine give full counsel for using it most advantageously for regaining health, strength, and mobility.

RANDALL'S SOLUTION FOR MORTAR

Supersedes Cement. Sets in Frost, and Hardens Stone or Brick-work.—RANDALL'S STONE CO., Kentish Town-road, N.W.

W. H. LASCELLES and CO.,

MERCHANTS,

120, BUNHILL ROW, LONDON, E.C.

The most extensive Stock of every kind of Wood in Planks and Boards, dry and fit for immediate use.

TENDERS.

. Correspondents would in all cases oblige by giving the addresses of the parties tendering—at any rate, of the accepted tender: it adds to the value of the information.

BOURNEMOUTH.—For house, stables, lodge, &c., at Canford Cliffs, Bournemouth, for Colonel C. Mercier. Mr. Reginald G. Pinder, F.R.I.B.A., Arcade Chambers, Bournemouth, architect:—

Hoare, W.	£5,131	1	8
George and Harding	4,625	0	0
Hammerton and White	4,465	10	2
Hayward, Penton, and Hayward	4,152	3	7
Buckingham, E., and Son, Winchester	3,992	17	0
Rest of Bournemouth.			

BOURNEMOUTH.—For schools, Gladstone-road, Boscombe, Bournemouth, for the Bournemouth and District School Extension Committee. Mr. R. G. Pinder, F.R.I.B.A., Arcade-chambers, Bournemouth, architect:—

Hayward, Penton, and Hayward...	£2,130	0	0
Kitcher Bros.	2,031	0	0
George and Harding	1,997	0	0
Jenkins and Son	1,794	0	0
Hoare, W. (accepted)	1,535	0	0
All of Bournemouth.			

BOURNEMOUTH.—For schools, Malmesbury Park, Bournemouth, for the Bournemouth and District School Extension Committee. R. G. Pinder, F.R.I.B.A., Arcade-chambers, Bournemouth, architect:—

Kitcher Bros.	£2,325	0	0
Hayward, Penton, and Hayward	2,335	0	0
Abley and Cowley, Salisbury	2,224	0	0
Hoare, W.	1,948	10	0
George and Harding (accepted)	1,911	0	0
Rest of Bournemouth.			

BATTERSEA.—For providing a coal lift at the Mantua-road School, for the London School Board:—

Smith and Stevens (accepted)	£54	0	0
------------------------------------	-----	---	---

BOW, E.—For extra cloakroom accommodation at Fairfield-road School, for the London School Board:—

Gregar and Son	£194	0	0
Neil, W.	183	0	0
Atherton and Latta	157	0	0
Gibb and Co.	157	0	0
Robey, J. T. (accepted)	152	0	0

BRISTOL.—For the construction of a gasometer of 5½ million cubic feet at Barton Hill, for the Bristol Gas Company:—

Aird and Sons, Lambeth (accepted).

BRISTOL.—For providing and fitting up machinery at the workhouse laundry at Stapleton, for the Bristol Board of Guardians:—

Bradford, T., and Co.	£516	0	0
Baker, W., Bristol	499	18	0
Strong, H. O., Bristol (accepted)	450	0	0

BUSHY.—For the carrying out of sewage outfall and disposal works for the Watford Union Rural Sanitary Authority. Mr. Urban A. Smith, C.E., Victoria-street, S.W., engineer:—

Dickson, J., St. Alban's	£7,722	4	0
Jackson, J., Plaistow	7,537	0	0
Neave, J., Forest Hill	7,533	0	0
Turner, T., Ltd., Watford	6,801	16	4
Cooke, B., and Co., Battersea	6,447	6	8
Wingrove, J. T., Northampton	5,749	0	0
Dupont, F., Colchester (accepted)*	5,738	6	3

* Corrected total.

CARDIFF.—For relaying the sewer in Corporation-road, for the town council:—

Ridley, T. D.	£1,706	0	0
Pearson, T. C.	1,627	10	0
Ailan, J.	1,464	11	0
Gregory	1,294	12	10
Strachan	1,240	0	0
Rees, T.	1,029	5	0
Ashley, F. (accepted)	906	0	0

DURHAM.—For the erection of two shops and eight-roomed house, &c., at Stanley, Co. Durham, for Mr. W. Aynsley. Messrs. John Smith and Son, Shotley Fridge, Co. Durham, architects. Excavator, bricklayer, and mason and carpenter, and joiners' quantities only by Mr. George Bell, 63, Collingwood-street, Newcastle-on-Tyne, building and quantity surveyor:—

Excavator, Bricklayer, and Mason:—			
Brown, H., and Co., Newcastle	£1,016	4	11
Routledge, A., Armfield Plain	790	0	0
Johnson, W., Flint Hill (accepted)	736	0	0
Carpenter and Joiner:—			
Brown, H., and Co., Newcastle	8'5	14	3
Haslop, J. T., Dipton	630	0	0
Mordue, T., Dipton (accepted)	619	10	0

GODALMING.—For the erection of works of main drainage, for the town council:—

Botterill, W. J., Cannon-street	£20,115	0	0
Neave, J., Forest Hill	15,451	0	0
Kavenagh, S., Surbiton	14,853	11	0
Facey, R. R., Taunton	14,056	10	0
Cooke, B., Battersea	13,900	0	0
Cunliffe, W., Kingston-on-Thames	13,747	11	0
Peters, F., Horsham	12,100	0	0
Morgan, Isled, and Morgan, Southampton	10,496	0	0

GODALMING.—For alterations to the town hall, for the corporation:—

Humphries (accepted).

LANDPORT.—For additions to the Bedford Hotel, for Messrs. Pike, Spicer, and Co.:—

Jones, H., Portsmouth	£2,160	0	0
Light, W. R., and C., Landport	2,045	0	0
Scammell and Dowdell, Landport	1,930	0	0
Corke, J. H., Southsea (accepted)	1,790	0	0

LONDON.—For rebuilding and extending the Bedford Institute, Spitalfields, for the Bedford Institute Committee (Society of Friends). Mr. Rutland Saunders, F.S.I., 6, Bishopsgate, Without, E.C., architect. Quantities by Mr. Walter C. Phillips:—

Ashby Bros.	£7,780	0	0
Hall, Biddall	7,500	0	0
Woodward and Co.	7,399	0	0

FRIDAY, NOVEMBER 18, 1892.

"THE COUNCIL BROADWAY."

FOR a long time past we have heard much of the "Council Broadway," but during the last two weeks we have heard even more than a great many expected. With the various schemes that have been submitted for the Strand to Holborn improvement will always be closely associated the "betterment" principles of the London County Council, the last phase of which was so prominently brought before the public in the report of the Parliamentary and Improvements Committees, which was discussed at such length by our municipal government a fortnight ago. The taxation of ground landlords throughout the County of London is but the extension of the "betterment" area to its utmost limits.

It is already a matter of history that the proposals of the Committees were, that if, instead of acquiring any property within the "limits of deviation," the Council should leave the same in the hands of the owner, then the owner of such property should contribute 50 per cent. of the enhanced value or special benefits conferred upon it. This 50 per cent., it appears, is proposed to be "secured by way of charge," and the value to be ascertained by an arbitrator, with power for the owner to "redeem such charge." In the preamble to the report it was stated that the Council had been advised that the enhanced values or special benefits conferred on property by new streets would in no case amount to any sum approaching one-half the net cost of the street. The next recommendation appears to us most fair, provided "betterment," irrespective of "area," is adopted, as it ought to be, as the right and proper means of raising the necessary funds for street improvements in the future—namely, the taking "into account in assessing compensation" of all improvements that have been made since the 22nd July last, "when the scheme was made public." It is well known to many of our readers that where land or property is thought to be "scheduled" by a public body, to be acquired for public use, there has been a strong temptation for the owner to "improve" the property, and thus enhance the value obtainable as compensation. We have nothing to do now with the arguments for or against betterment, but we do think that the public pocket should not be drained upon to compensate for what has been only created for the purpose of compensation. It is some satisfaction, however, that this class of speculator is sometimes caught in the toils of his own net, for we have heard of buildings still standing in this Metropolis which were erected in order that they might be bought by public money to be pulled down.

The third recommendation of the Committees, which was adopted with an addition in the form of an amendment, suggests the new and wider area of "betterment," to which we have already referred. In this it is advocated that a moiety of the cost of the improvement should be paid out of "any new rate to be imposed by Parliament on the Metropolis as a *Land Values Improvement Rate*, to be charged as in the nature of a land-tax in respect of the ground values of property within the County of London"; such rate, it was mentioned in the report, should be charged upon the owner, and not be capable of being made "the subject of contract, so as to shift the incidence thereof." With a view to the introduction by the

Government of a Bill dealing with the subject in the ensuing session, the Committees recommended that a communication should be made to the Local Government Board. These recommendations, with instructions to the Parliamentary Committee to embody in a separate Bill provisions for creating an "improvement rate or charge on owners of property," to create a moiety for the cost of the "Council Broadway," were adopted by the London County Council after a lengthy discussion at their meeting on the 8th inst.

The legal advisers of the Council seem to have pointed out that "the charge" cannot be imposed upon owners of ground values of property within the County of London by private Bill, but must rest on a public Bill, and that the Bill to be promoted by the Council relating to the "Council Broadway" should contain a provision that if any such *Land Values Improvement Rate* were created by Parliament next session, a sum not exceeding an annuity—to be calculated, and to be equal, on the £3 per cent. tables payable half-yearly for a term of 60 years, to a sum of £1,123,000—might be charged upon and raised out of such *Land Values Improvement Rate*, in respect of the cost of this scheme. Such rate, it is estimated, would have to be at least one penny and a fifth in the pound on the estimated ground values of the Metropolis.

It is not for us to deal here with the probabilities of the suggestions being acceptable to the present Government; it is well known that "betterment" was not looked upon with a favourable eye by the last Parliament, and no one can surmise the fate of the present, and enlarged, scheme. Nor do we pretend to anticipate what will be the exact course taken by the Council—whether they will adopt the introduction of a Government measure, as recommended by the Committees, a private Bill, as embodied in the amendment, or both. Let it suffice to point out the absolute necessity for the speedy construction of a new street from the Strand to Holborn. How it is to be paid for is a public, more than an architectural, problem; but how the street, when formed, is to be developed, is a matter that concerns the architect, and so important did the President of the Royal Institute of British Architects consider the subject, that he devoted a considerable portion of his address at the opening of the present session to the consideration of the subject.

It will be remembered that the proposed "Council Broadway" is to be a street 100ft. in width, running from St. Mary-le-Strand northward to High Holborn at a point exactly opposite Southampton-row. At the Strand end the road diverges east and west, Holywell-street disappears in the widening of the Strand, Blackmore-street and White Hart-street are widened, and at a point where Sardinia-street now stands it is proposed to form a circus. Four large buildings are partly or wholly destroyed, the Electric Lighting Works in Sardinia-street, the Board school in Vere-street, and the Olympic and Globe Theatres.

Commenting upon the proposal, Mr. MacVicar Anderson drew attention to the "happy thought which ought to conduce to the convenience of the public" in the divergence of the traffic from the north to the east and west at the southern extremity of the proposed street, instead of discharging it at a single point in the busy thoroughfare of the Strand. "The expediency, however," he said, "of laying out the street on the central axis of a line drawn northward from the centre of St. Mary-le-Strand appears to be open to doubt. The Church of St. Mary was designed, as we know, to be viewed from the west and east, notably the former, where it forms so charming a feature in the street architecture of London; and from an artistic point of view it is questionable whether it is wise to make it the central feature of a northern thoroughfare, to which it would

present a frontage not designed for such a purpose, with the tower and steeple to one side instead of being in the centre of the vista from the north." There is much in the suggestion that Somerset House should form the central feature, that will meet the approval of all architects.

The improvement of the thoroughfares of this Metropolis, with a view of relieving the congested and ever-increasing traffic, is a subject of vast importance to architects and citizens alike, and the President did well to remind the Institute and individual architects of the responsibility upon their shoulders in endeavouring to "educate public taste by adorning a public thoroughfare," responsibility not to clients only, but to the public also, "for," said he, "such buildings cannot by any possibility remain inoperative, they must exercise some influence for good or for evil on the minds of men, and in proportion as they inspire by truth and purity, and create correspondingly elevating emotions, are they entitled to rank as works of architecture. Apply this test to one of the most important modern thoroughfares in London."

The problem of rehousing the artisans displaced by the demolition of property to form new streets is a grave one, which has no doubt received fully the consideration of the Council, and we are informed that with the exception of 470 whose work and occupations necessitate their being rehoused on the spot, and of 800 whom it is necessary to rehouse within a mile of their present residence, it is contemplated to remove 1,800 of the working class population to the suburbs, a provision which helps to relieve overcrowded London, and permits of a healthier mode of living.

The estimated cost of this scheme is—for the removal of Holywell-street and construction of the new street, £1,870,000; the widening of Blackmore street and White Hart-street, £130,500; the widening of Wych-street, £25,500, making a total of £2,026,000. With such large sums of public money at stake, it is for architects as a body to see that uniformity and harmony are exercised in the carrying out of the architectural treatment of a thoroughfare that should be one of the finest in the world. It would not be correct to say that such opportunities had never occurred before, when we remember what might have been done with Northumberland and Shaftesbury Avenues. Mr. MacVicar Anderson reminded his hearers that so noble a thoroughfare as that contemplated by the Council would afford a worthy field for the display of architectural skill; and, referring to the power required by the Council to control the architectural elevation of the new street, he said that, should this mean that the control is to be real—and not visionary, as in the case of Northumberland avenue—and that it is to be exercised by persons competent to deal with the subject, we may regard the proposal with satisfaction. It is most sincerely to be hoped that the Council will leave the responsibility of the approval of the designs in the most competent hands—indeed, it appears to us that such an important question as the approval of designs for such a thoroughfare through the heart of this vast city should be left to a small representative committee of the greatest architects of the age, and that such a committee—say, of three (the smaller the better)—should be drawn from the ranks of the Royal Academicians and the Royal Institute of British Architects.

In designing the buildings for the World's Fair of Chicago, the American architects employed have endeavoured, without sinking their individuality, to attain a harmonious whole, under the directing hand of one leading architect. This principle appears to us to be one that, in a measure, should be adopted in such a national undertaking as the "Council Broadway." All architects

obtaining commissions to erect buildings upon sites bordering upon the new street, should submit their designs to the criticism and direction of the representative committee we have suggested; then, after consultation with them, and following the probably good advice they would receive, we could reasonably expect to have streets with buildings, while devoid of monotony, harmonising its entire length, instead of a conglomeration of structures, as in Shaftesbury-avenue, which, the President of the Institute suggested, created no emotions in a cultured mind other than those of irritation and disgust. "Buildings they are, certainly—architecture they are not."

May we look to the Council themselves to lead the way in the true artistic improvement of our streets? It is hoped we may, for it is no secret that in years to come a Council of the future may choose to erect in Council Broadway an hôtel de ville worthy of so powerful a body. It is well known that the present offices of the Council are quite inadequate for the staff required to carry on the many duties of this body. There cannot be many more years of delay before London has a town hall. When almost every provincial town throughout the kingdom can boast of such a building, it is strange that London has to do without; but this is not the only anomaly that the Metropolis suffers from. When it does come, let us hope that the county hall and offices may form a building of no mean architectural merit, and be the keynote for the harmony of the Council Broadway.

DIVISION OF BUILDINGS.

THE important statutory provision that a building devoted to commercial purposes should not have an unrestricted space of more than a certain cubical capacity is not very clearly understood, if we are to judge from the frequent instances in which the law has been broken or tested. Every now and again we hear of summonses being taken out against builders of premises who have exceeded the limit of 216,000c.ft. in respect of buildings of the warehouse class, the contention raised in reply being that the building came within the class of dwelling-houses. The question has usually turned on the meaning to be attached to subsection 4 of the 27th section of the Metropolitan Building Act, where it is laid down that "every warehouse or other building used either wholly or in part for the purpose of trade or manufacture, containing more than 216,000c.ft., shall be divided by party-walls in such manner that the contents of each division thereof shall not exceed the above-mentioned number of cubic feet." Now, it is obvious that the question rests upon the meaning of the words "or other building used either wholly or in part for the purpose of trade," &c., a phrase which is wide and elastic enough to include a vast number of buildings that are not certainly warehouses, but are used partly for trade and partly for dwelling purposes. A lawyer would have no scruple in including in this category every kind of business or shop premises where the building contained only one floor as a shop, and all the other floors as dwelling rooms, and we cannot be surprised that Mr. Vaughan, the other day, decided that certain extension of business premises, additions to Messrs. Shoolbred's Tottenham Court-road establishment, came under the above section of the Act. The circumstances of that case we have already reported (page 654). Here was an important building in Grafton-street of eight stories, 87ft. in height, the total cubical contents of which were 272,800ft., exclusive of the staircase, which added 16,656ft. An iron and concrete floor at the fourth floor level divided the building, it would appear, horizontally, the contents of the rooms above the

floor being 62,087ft.; but this floor of iron and concrete was pierced by four openings for lifts besides the staircase. The basement is to be used for packing goods, the ground floor as a shop; but the upper floors are intended to be occupied as dining-rooms, scullery, and kitchen offices. The chief question in this case is whether a horizontal division by a fireproof floor constitutes a proper "party-wall" or an equivalent to one between the lower and upper portions. If we deduct 62,087, the cubical contents of the upper rooms, from the total 272,800ft., it leaves 210,713c.ft., which is within the statutory limit, and it has been assumed that, therefore, the building conforms to the requirements. We have here an important point brought again to the notice of the profession, whether a building divided by a fireproof floor is equal to one divided by a vertical or party-wall. We hear that it was decided some years ago in the affirmative in connection with a previous building carried out by this firm.

A large number of buildings in towns, especially in London, are what we may call "composite"—that is, erected for the purpose of more than one occupation or business. In the City we have large structures built primarily for offices, let in flats, but having retail shops and stores on the ground-floor and basement, and above offices, bedroom accommodation, kitchens, and lavatories. Broadstreet, Lothbury, Cornhill, Cannon-street, Chancery-lane, Victoria-street, Westminster, are filled with buildings of this composite kind, as they are found to be more remunerative owing to the heavy ground-rents. We cannot place these buildings in the category of warehouses; they are mainly residential, but the basements and ground-floor stories often contain a large quantity of combustible goods. Is it carrying out the intention of the Act to construct a fireproof floor of iron and concrete between the shops and the premises above, with the intention that each division should not exceed the 216,000c.ft.?—or should more frequent party-walls be built through the whole block vertically? This is one of the questions raised. If the law only takes cognisance of two distinct kinds of buildings—*warehouses and dwelling-houses*—and leaves the composite building, such as we have described, out altogether, then we can understand why so many buildings of the latter class are not interfered with, and why buildings may be half warehouses and the other and upper half dwellings. But this obviously is not the intention, for the same section provides that separate sets of chambers tenanted by different persons shall be divided so far as they adjoin vertically by party-walls, and so far as they adjoin horizontally by fireproof floors, when such sets exceed 3,600sq.ft. The horizontal division, then, is not unrecognised in these cases, nor does it appear that it is in the case of the composite class of buildings named, for the horizontal fireproof floor was, if we mistake not, decided to be equal to a party-wall in a case brought before the magistrates some years ago. Subsection 4 of section 27 is, as we have said, elastic enough to include the composite class of buildings; but then it may be argued that the section only applies to buildings intended for warehouses, as nothing is said about dwelling-rooms—that is to say, it applies to a warehouse that may be only partially used for the purposes of trade or manufacture. The clause at least is not so clear as it might be, as it should distinctly define how much of the warehouse accommodation or floors for goods or storage should be permitted in a given building to make it a warehouse under the Act. The term "wholly or in part" is ambiguous, for it implies that if only one floor or room of a building is used for trade or manufacture, and the other floors be dwelling rooms or offices, the section is to take effect, and there-

fore that every block of offices or residential chambers is amenable to the limitation if any portion, however small, is used for trade. At any rate there is a great difficulty in ascertaining where a building of a composite kind exceeding the statutory cubical capacity is really exempted from the operation of the Act, and it is upon this ground that an amendment is called for. The clauses in the Consolidation Bill proposed except certain buildings, and the L.C.C. in its General Powers Act may, if satisfied on the superintending architect's report, and that of the chief officer of the fire brigade, that larger dimensions are necessary for the purpose of trade or manufacture, not involving the use of inflammable materials, and that arrangements for lessening danger from fire are made—may consent to larger dimensions, but in no case is the building to have a greater cubic capacity than 450,000ft., or be above 60ft. in height. We do not complain, however, of the limit already in force for warehouses, but for other buildings of a composite character the clause as it now stands is vexatious. The party-wall division is unquestionably a safer mode of preventing the spread of fire than the horizontal fireproof floor, although there are circumstances which render the latter kind of division essential in all buildings occupied partly by trade and partly for habitation. Large hotels with shops on the ground floor and large blocks of flats let out for shops on the same floor are instances which require the horizontal division of space, of course without any openings for lifts.

One question having a decided consequence in all future buildings of this kind has been raised in this case, and the profession will wait with interest the result of the appeal that has been granted to Messrs. Shoolbred. What is a warehouse? is the question that has to be settled once for all. It may seem strange that after so many years of building in London since the year this clause was framed (the 18 and 19 of Victoria) builders and architects should be so continually making mistakes, and it is also strange that buildings are allowed to be commenced, and far advanced, before irregularities are discovered. In this instance the application was made for a building of the dwelling-house class; plans were submitted with walls of the required schedule thickness, and it seems curious at least that the mistake was not pointed out at this early stage, before the building was commenced.

"WHAT HAVE WE TO DO WITH THE BEAUTY OF LONDON?"

THE London School Board had a discussion last week on the design for the extension of their offices on the Embankment. Their architect considers that, to complete the proposed long frontage in a satisfactory way, a tower is absolutely necessary; and he proposes to make it useful as well as beautiful. The Works Committee of the Board had approved it, and the great majority of speakers were in favour of it; but, on a division, the matter was referred back to the Committee for further consideration. The alleged reason for objecting to the tower was its cost, which is estimated at the moderate sum of £3,000, out of the total expense of £220,000. The mover of the amendment to reject it alleged that at ratepayers' meetings this clock-tower would be "flung in their faces," and a supporter of it said "they were asked to spend this money so as not to impair the beauty of London. What had they to do with the beauty of London?"

We agree with the last speaker that it is a monstrous thing for him, or anyone like him, to "have to do with the beauty of London." It is a blot on our civilisation that anything noble or admirable should lie at the mercy

of the pennywise and the pettifogging. Unfit to decide on questions of art, they are equally unfit to be trusted with matters of education. It is they—always eager for the halfpence that can be picked out of the gutter, and always incapable of seeing the sovereigns that might be gained in cleaner places—who have done so much to make national education a curse instead of a blessing. It is they and their class, with its inborn want of imagination, who impose, or seek to impose, one dead uniform type of training on millions of children, each with his own special aptitudes and tastes and capabilities—the training that qualifies a boy to become a junior clerk. They have turned out half a world-full of junior clerks, till every advertisement for one is answered by hundreds, almost thousands. They have brought junior clerks and senior clerks almost to the verge of starvation, and the pressing problem with wiser men is how to undo their handiwork? Here, at the same moment, we see everything like workmanship declining or threatening to decline for want of able workers. Germany is beating us in technical thoroughness, France, and even Japan, in artistic thoroughness, and America in invention and power of adaptation. England must match and over-match them, unless she is to sink into a second Holland. It is time, indeed, to set up technical schools, and to make art schools into a more real power than they have ever been yet, or before long even the pettifogger will feel the pinch—in the only sensitive part of him—his pocket. In the mean time let him at least keep out of the way. The times do not need him, any more than they need the miserable legion of unemployed clerks which his obtuseness has produced. They need the workman, and the art workman, and both workmanship and art workmanship have ranged themselves in all past ages, where they are likely to range themselves in all future ones—round the art of building. "What have we—the London School Board—to do with the beauty of London?" It is the utterance of a man talking in his sleep—a Rip Van Winkle who will be roused by-and-by. "You have everything to do with it," is the answer of those who are awake. "You have to preserve it where it comes in your way, you have to train up children who can appreciate it and add to it. You have trained enough starvation clerks; open your eyes and see what you may learn to better purpose."

So much for the type of mind, or of mindlessness, which cannot realise that those who are to succeed in the arts ought to grow up amidst artistic surroundings. It does cut, to every child alike, a little reading, a little writing, and a little arithmetic, and thinks that these things—and these alone—are the "rudiments of education." It starts with a sort of vague belief that nobody, in the good time coming, will need skilled hands or strong sinews. It tacitly assumes that when people everywhere know something about words and something about figures, Nature will kindly give them all they want, without any need for manual exertion. The working man is to cease. His descendants will be superior to the necessity for labour. The human race will write or lecture, or sit at desks on four-legged stools, keeping accounts, and in this way they will get a genteel living. No one will be degraded by having to lay bricks, or to work stone, or to shape timber. Education will do away with the mechanical trades. There will be a millennium of black coats and chimneypot hats, and we shall all belong to the lower middle classes. That is the vision of delight which dances unsteadily before the dreamers who "have nothing to do with the beauty of London." It is a vision that can never be realised. Now, as of old, it is hard labour to make bricks, hard labour to carry them, hard labour to lay them; and yet houses will not spring up by

themselves, though the whole population had the training of a senior wrangler. Now and always, as far as human foresight can discern, the majority of men will need physical strength and mechanical skill. The three R's will not save them: in the sweat of their brow they must earn their bread.

It is the great merit of the artist that he sees this fact, and is prepared to deal with it. It was never his ideal to take all men out of flannel jackets and put them all into shoddy coats. His notion of elevating the masses is not to turn the top of the working class into the bottom of the trading class—to make the carpenter into a small shopkeeper, and the mason into a jerry builder. He sees—what the anti-artist cannot see—that there is a limit to this kind of thing. If he is a Radical, he is such a Radical as Felix Holt, who did not think that the chief end of man was to have three steps to his door, and a brass knocker above them. He is sure that a workman may be just as good, just as cultured, and just as refined as anyone else, and that he may become so through the work he has to do. He would raise him now as he was raised in former times, by making him, in his own sphere, an artist. He would show him how to do his work in such style that all educated people shall admire and be in sympathy with it. He has made up his mind that the amount of respect due to a man ought to depend on *what* he is, and not on *where* he is, and, being quite sure about this, it does not trouble him that a large part of the human race will always have to be where—or not very far from where—the best of the working class is at present. Thus the artist's is a practical ideal, while the anti-artist's is not. It is so, even from the commercial point of view. The anti-artist's notion of elevating a child is to put him out of his own rank into what the popular prejudice of his day counts as the rank above it. For a little while, this may succeed. One mechanic's child, or a hundred such, may rise—if it is a rise—to be clerks or tradesmen, and may find themselves earning more money so than their fathers did before them. But this process cannot go on for ever. When many, or most, mechanics' children come to attempt it, the profits fall, and the end is that they gain less money and have heavier expenses than if they had remained in the rank from which they set out. The world is not calling for more clerks or more tradesmen. But it is calling for better work, for more inventive work, and for more artistic work. For these things it offers better pay, as well as more personal consideration. In producing them lies the hope of the English working class. To train its children so that they may be fit to produce them is a most urgent duty of English School Boards, and they cannot be trained to any purpose amongst starved, sordid, scamped surroundings. The art workman, if he is ever to come near his full stature, must grow up from childhood amongst beautiful things. His schools should be beautiful within, his cities beautiful without. It is only in such surroundings that admirable work, on any large scale, has ever been done. And now, when by the labour of generations, and the expenditure of millions, something has been accomplished towards making our greatest city beautiful once more, there are actually managers of public education who cannot so much as let it be. They are told that they will destroy the beauty of that riverside terrace which has been shaped into some picturesqueness, and which has many possibilities of more, and they grunt out in reply, "What have we to do with the beauty of London?"

We come to an aspect of the case which even Mr. Pennywise may open his eyes to. He has, or professes to have, a terrible dread of the ratepayers. They are a long-suffering race; but once in a while they do stand up and kick when the burdens laid on them are

more than they can bear. Waste and folly are the things that crush them down; and for waste and folly the round world does not hold the match of Mr. Pennywise. Take the case of the very building under discussion, the School Board offices on the Thames Embankment. Thousands of pounds have already been spent to make it architectural. Consistent penny-wisdom would have kept it, from first to last, as plain as a pikestaff, and would have saved all this money. But penny-wisdom never is consistent. So it begins by aiming at an architectural work. It takes a great deal of trouble, and goes to a great deal of expense—an expense borne by the ratepayers—to produce such a work. Having produced it, the necessity arises for enlarging it; and then penny-wisdom thinks that the idea of keeping it architectural had better be given up. It has spent thousands of pounds out of the rates to make the offices an artistic success; and then it proposes, as an economy, to do what will effectually destroy such success as has been attained. It coolly recommends that all these thousands should be wasted and go for nothing; and then it turns to the ratepayers and says, "See what a friend you have in me! See what a saving I am going to effect!"

Penny-wisdom, such as this, runs more or less through all the public management of England, from the village vestry to the Treasury Bench. More than half the candidates for every office, high or low, seek support by promising to save sixpence in ways which will waste a shilling. Take one way, familiar enough to all contractors for public works. The Government decides, some year, on building a large structure,—say a barrack or a hospital,—to cost a £100,000 or so. It would look extravagant to ask for all this money at once, and get the thing done. So, to make a show of economy, only a small vote on account is taken, perhaps for £10,000, and the works are begun. Next year another Government is in power, having carried the elections by glowing promises of retrenchment; or the old Government remains, but is seized with a saving fit. No more money is voted that year or next. The frost gets into the unfinished brickwork; the water saps the undrained foundations; the walls get pushed over by children and idlers; the hoardings and scaffolds decay, and are destroyed. When at last Parliament votes more money, the work which was paid for previously has become almost worthless, and the contractor makes heavy claims for loss of plant, and perhaps for loss of time. In one way or another, the first £10,000 is gone,—with nothing to show for it: and this is what penny-wisdom counts as economy. Look at another case of the same sort, which occurred in the last generation, but whose consequences may well be seen. The Houses of Parliament were just being begun. The Government of the day had appointed a distinguished commission of men eminent in geological knowledge and practical building to inquire into and report on all the principal building stones of the kingdom, so that the very best kind might be adopted for the great national work. After immense trouble and expense they issued their report—a very thorough and valuable one, and they recommended the Bolsover or Church Anston stone which has actually been used. How is it, then, that for more than thirty years past the masonry at the Houses of Parliament has been perpetually decaying? We owe it to the Pennywise of the period. The quality of Bolsover stone, like that of most others, varies in different parts of the quarry. The best is admirable, and the worst is execrable. A clerk of works had been appointed, at a very moderate salary, to live at the quarry, and to make sure that only the best beds were sent up to London. But when the £150, or thereabouts, which was to be paid him yearly,

appeared in the Parliamentary estimates, some patriotic soul protested against it as a waste of public money. The Government were weak enough to yield; the clerk of works was dismissed, and for his age-long monument, that patriotic economist has the mouldering plinths and cornices of the Palace of Westminster.

Such things may be done in Parliament. Our system of party government is an encouragement and a protection to them, and electors have to sit and see them done without being able to interfere. But it is not so on the London School Board, which has not, as yet, become a servant too powerful for its masters. Those masters are the people of the metropolis. Public improvements are their property, and have been paid for with their money. And when any servant of theirs boasts that it is no business of his to avoid spoiling these improvements, he is plainly above his work and unfit for his place. To ask, "What have I to do with the beauty of London?" is to make it clear to everybody that London and he had better part.

THE SOCIETY OF ARCHITECTS.

THE ninth session of the Society of Architects was inaugurated on Tuesday afternoon by a meeting held at the Society's rooms, St. James's Hall, Piccadilly. The President, Mr. Robert Walker, of Cork, occupied the chair. Mr. ERNEST DAY, of Worcester, Vice-President, proposed the adoption of the report of the Council, of which an abstract was published in our issue of the 28th ult., p. 588. He congratulated the members on the lucid and encouraging character of the report, and remarked that there was a deficit of 15 guineas in a total income of £1,100; but it included several items of expenditure, such as those of incorporation, that could not recur, and there is a substantial balance of assets over liabilities. Mr. E. TIDMAN, treasurer, seconded the motion, which was carried unanimously. A vote of thanks to the donors to the library was proposed by the ex-president, Mr. W. H. SETH-SMITH, who remarked that every year saw an improvement in the library, which was now well housed and arranged. He appealed for donations of additions to the volumes from members and their friends. This was seconded by Mr. J. W. FRAZER, of Newcastle-on-Tyne, vice-president, and was agreed to.

The following gentlemen were elected:—As an honorary member, Rev. John Edward Field, M.A., Benson Vicarage, Wallingford; as members, Edward Coath Adams, 11, Great James-street, W.C.; Philip Condry, 9, Newcomen-street, S.E.; John Wordsworth Darwent, Ramstorth, Ecclesfield, Sheffield; Leonard James Kempster, 341, Strand, W.C.; and Frank Lovell Lee, 14, Gray's Inn-square, W.C.

The President then delivered his

OPENING ADDRESS.

Having acknowledged the honour conferred upon him by election to the chair for the third time, Mr. Walker paid a handsome tribute to the valuable services rendered by his immediate predecessor, Mr. Seth-Smith, and continued:—In accepting the trust, I bring to the discharge of the duties involved a renewed confidence in the willingness of the Council and Officers to labour for, and in the loyalty of the members in promoting, such measures as we believe to be for the best interests of our profession, in relation to architectural art and practice, and in relation to the public whose interests we profess to conserve; and this you have endeavoured to do, through evil and through good report, since the inception of the "forward movement" which called you into existence as a society, and which movement you have supported and which you will continue to support, earnestly and persistently, but inoffensively, until the progressive bark is conducted safely into smooth waters: under the strong conviction that the measures which you seek to promulgate will develop true architectural art. And I wish to add emphatically that the supporters of the "Architects' Education and Registration Bill" who number into the tens of hundreds inside and outside of this Society, only hope to participate in the advancement of architectural art and practice which its passing will

most certainly inaugurate, in common with those who, for the moment, regard it with apprehension or hostility, and whose numbers are, so far as our information enables us to form an opinion, a constantly diminishing minority. If there be any who indulge in the selfish hope of special and undue advantage arising from the passage of this Bill through Parliament (and rumour, from probably where the east wind rises, says there are such), it will prove to be a delusive and vain hope never to be realised; but the charge, if it ever were seriously made, may be dismissed as a weak device intended to injure the measure, and may be regarded as the creation of an unscientific imagination which never seeks for a foundation to build on. It is what lawyers call a constructive case, resting upon the same sort of basis as the castles in the air, which the boy in the Scotch song built on as he looked into the puffing low (fire), following the example of "many mighty men"; but in this case he is the prototype. Your council's report contains a review of the past session's work, and gives the statistics of your financial and numerical growth. Your printed proceedings give your secretary's (Mr. Middleton) clear narrative description of the Society's tour into Belgium last year. I regard these tours as times of learned leisure, where some with pencil and some with pencil and palette fix in their sketch-books excellences of plan, elevation, and grouping, beauties of form and colour, and effects of lights and shadows. On the last occasion that it was my privilege to address you from this chair, I suggested that the Architects' Education and Registration Bill Committee, which was appointed in 1886 by a conference of delegates from the three kingdoms, should collect what had been written on both sides of the question it had in charge, eliminating irrelevant matter, and reissue it in the hope that it may reach the apathetic and indifferent, and induce them to give the measure due consideration, and finally their support. This suggestion has not been acted on, and owing to the general desire that has been expressed for information as to the nature and present position of the measure, and the prospects which the outlook portends, it seems fitting that I should shortly refer to the objects of the Bill, and its method of dealing with acknowledged evil, as I fear many have never read it, and others, having read it, have forgotten its scope and the nature of its provisions. There is a saying in the North, whence many of our sturdiest plants in the arts, sciences, and literature have sprung, that "Ill weeds will up." A condition precedent to eradicating them is to clear the ground, amongst other measures, and this is ever a slow process, demanding care and patience. Speaking figuratively, the plantation of architecture is invaded by this evil, and the object of the measure before Parliament is to clear the ground so that the seeds of education may have freedom to grow and strengthen, yielding a fruitful harvest of good architectural art when the harvest-time is reached. Ages ago it was said that you cannot root up the tares without injury to the grain, and the husbandman must bear with the result of his neglect which fostered the growth of the two together until the harvest. The evil of incompetence amongst architectural practitioners has been sufficiently exposed in your printed proceedings, in the professional journals, which have done good service in this direction, and in the public press for the last 32 years, since the passing of the Medical Act, which deals with a singularly analogous state of things to that which architectural art and practice suffers from at the present time. The promoters of that Act endured 30 years of contumely, fierce personal abuse, and unreasonable and unreasoning opposition, vile aspersions and unblushing misrepresentation; even the truth, when, through the stress of circumstances, it had to be touched by their opponents, "was handled carelessly," to borrow a picturesque grouping of words from our American cousins. Through all this unsavoury trial, inflicted by selfish and narrow-minded foes from within the ranks of their own profession, the promoters waded prior to the passage of their Bill through Parliament in 1858. As it emerged from the portals of the Upper House, Lord Elcho said, "You have got it, gentlemen, after 30 years' struggle; I hope it will be of some use to you." It certainly bore the marks of the conflict in scars and mutilations, which the wisdom of Parliament has been engaged in amending periodically ever since, and in adding Amendment Acts due to the growth and development

of education, which ever moves forward, creating new necessities, and to the result of experience and increased knowledge. And such, I apprehend, will be the conditions that await the Architects' Education and Registration Bill when it takes its place in the Imperial Statute Book as an Act; there will be no limit to the free growth and "Advancement of Architectural Art and Practice," fostered by wise provisions for the discovery and development of aptitude, cultured attainments, guidance in education, general and artistic, technical and special, supplying to genius an equipment of training which will bear fruit, differing in degrees of excellence in proportion to the possession of natural gifts by aspirants. If the Bill passes its second reading in its present form, which may be said to be likely, as its principles are unassailable, the next stage is the Committee stage for the consideration of its details, which will then be very properly submitted to close scrutiny, and will be liable to modification and amendment; when opponents as well as supporters will be face to face with the public whose representatives constitute the House of Commons, which is the final authority to mould its clauses and give force to its provisions, taking care that they are in harmony with the public interests and on the lines of strict justice to all parties concerned. It has been pointed out by the promoters of the Bill—(1) That it is expedient that persons requiring professional aid in architecture should be enabled to distinguish qualified from unqualified practitioners; (2) that the necessity for higher qualifications in persons assuming the functions of an architect has been acknowledged by the profession and observed by the public for a great many years; (3) that persons without any training in art, science, or technical education whatever may and do practise as architects, and that a large number of persons are now so engaged is unquestioned; (4) that want of due qualification on the part of persons so employed is not only injurious to architectural art, but may result in injury to life and health, discomfort, pecuniary loss, lawsuits, embarrassments, and much loss and damage, without a remedy; (5) that public attention has been called to the evils of incompetency for the last 30 years, and efforts have been made from time to time to induce professional bodies to take up the question and deal with an ever-increasing evil, alike injurious to the interests of the public and the profession, and absolutely discreditable to the latter, but without avail; (6) that the number is largely increasing year by year of unqualified practitioners whose conspicuous want of technical knowledge and architectural art training is bringing the profession into contempt; (7) that this state of things has promoted the practices of proprietors carrying out works without the aid of an architect (which, of course, under the Bill they will have a perfect right still to do), there being no guarantee that the required knowledge would be possessed by the practitioner who may be consulted, in a profession, where the function may be assumed without any training in architectural art, or technical or other education of any kind whatever having been acquired prior to the assumption, and experience pointing to the probability that the necessary qualification would be absent; (8) that members of the profession, inside and outside professional bodies, seeing that the evil was becoming so increasingly manifest that the public themselves would be driven to call for a remedy, and considering that reform in any profession should proceed from within, and desiring to remove the odium which the absence of architectural art education entailed, resolved to take action in the matter. Accordingly, in 1886 a conference of architects was summoned by advertisements in the professional journals and 6,000 circular letters, to meet, on April 6, at the Freemasons' Tavern, London, which was largely attended by practitioners from all parts of the United Kingdom, at which resolutions were passed in favour of seeking Parliamentary powers to deal with the evils complained of and for educational purposes, and a committee was appointed to give effective force to the resolutions. Those members of the committee who agreed to act, proceeded to discharge the duties imposed upon them. Having considered the question, and prior to drafting a Bill, the committee, in August, 1886, to further test the feeling of the profession, sent out 2,500 circulars to the best-known members of the profession in the form of a declaration, *For or Against*, seeking legislative powers. 1,300 were returned signed and approved *For*, and only three wrote expressing

doubt or disapproval. A Bill was then drafted with due regard to Parliamentary precedent and form, which was submitted to Parliament, read a first time and withdrawn, owing to the fact that the Royal Institute of British Architects, Institute of Civil Engineers, and Surveyors' Institute, through their respective Councils, declined to be dealt with under the same Bill, and objected generally to the measures. To conciliate the strong opposition, which was unexpectedly hostile, the committee remodelled and recommitted the Bill in the form of the Architects' Education and Registration Bill, omitting from its purview civil engineers and surveyors, but introducing a compensation or exemption clause to meet the exigencies of such exclusion. To the late Lord Beaconsfield the saying has been attributed that "life is a system of compromise," or words to that effect; but it is to be observed that some men appear to be unembarrassed by the possession of any other faculty than that of the power to object. It is an absorbing faculty and consistent; it admits of no coquetting with any other faculty that may consciously or unconsciously impair its unyielding force; and so with a consistency that is marvellous in its indifference to appearances, the Amended Bill, amended to conciliate the vehement hostility to the inclusion of civil engineers and surveyors, was met with even more vehement hostility from the same quarters on the score of their exclusion. The Bill so modified is the Architects' Education and Registration Bill, now "hung up" in Parliament, waiting for the opening of the first session. I have sufficiently indicated its necessity and objects. If fuller information on the subject be desired it may be found in the printed Proceedings of the Society of Architects, in lectures in the professional journals, and in the Bill itself, all easily procurable. I wish to refer briefly to some of the main provisions of the Bill, and first let me say that some misconception has arisen from the short title given to the Bill, for which the promoters are in no way responsible. It was given to it when it was presented in the House by one of the clerks at the table. The short title in the body of the Bill is "Architects' Act," and is used only for the purpose of citing. The Bill provides for a council which shall be styled "The General Council of Architectural Education and Registration of the United Kingdom" (with branch councils) consisting of the following members:—Five persons nominated by Her Majesty with the advice of her Privy Council, three for England and Wales, and one each for Scotland and Ireland; five by the Royal Institute of British Architects, one by the Royal Academy of Arts, one by the Royal Institute of Architects, Ireland; two by the Society of Architects, two by the Architectural Association and its affiliated societies, five by provincial societies, nine by direct representatives, five for England, two for Scotland, and two for Ireland. The position of the professional bodies remain undisturbed, their powers are strengthened and confirmed, vested interests are recognised, and the public interests are safeguarded. Any or all of the clauses are open to amendment or modification. All persons who, prior to a date to be fixed in the Act, were actually in practice as architects, are, under certain reasonable limits of proof, admitted to register; and, after that date, all aspirants must comply with the educational requirements of the Act before being registered, for which a fee will be charged, the same as is provided in other similar Acts, to meet the expenses of administering the Act. It will also create a fund to be devoted to lectureships, examiners, art and technical education, the establishment of a museum and library—in fact, all that will go to build up a school of architecture and provide a teaching body to co-exist with an examining body. If this Bill be passed there is little doubt but that chairs of architecture in all colleges would be established; two now only exist. I have to say generally that this measure will regulate architectural education and practice; it will check the growth of incompetency by guiding the education of aspirants to the profession from as early a period as possible, helping them to discover special aptitude and genius, and, perhaps a still more valuable service, helping them to discover their absence. The vested interests of persons who may be said to be incompetent can only be dealt with as the Bill proposes, for Parliament would not tolerate any other method in dealing with incompetent persons in an

established practice. It was the opposition to a similar clause which retarded for so many years the passage of the Medical Act, which was ultimately passed, including this clause, by a majority of nearly 3 to 1. The Bill disturbs none of the recognised bodies, but it provides for the gradual extinction of incompetency by making it compulsory for all future architects to give evidence of having received special training and education—a stipulation which is so obviously reasonable and so calculated to produce the maximum of results, and is so universally acknowledged as wise and prudent, that there is no department of life-work to which the principle is not applied or ought to be applied. The Bill is now in the charge of Mr. L. Atherley-Jones, M.P., under whose able guidance all that is practicable will be done to advance it through its remaining stages; the best assistance that can be rendered to Mr. Atherley-Jones will be an exhaustive and free criticism of the clauses of the Bill, giving instances to prove its necessity or otherwise, with a view to approval, modification, amendment, or excision, communicated through Mr. Edgar Farman, 37, Walbrook, E.C., the hon. secretary of the Bill Committee. Having referred to the World's Congress of Architects to be held at the Chicago Exhibition in August, 1893, the President added: I have received from the Royal Victorian Institute of Architects a draft outline copy of their "Bill for the Registration of Practitioners in Architecture," which Bill has been made a Government measure; also an extract from the address of the President of the Institute in support of the Bill, which is an Architectural Education Bill, similar to the Bill before the British House of Commons; there is no doubt but that under such favourable auspices it will pass the Colonial Parliament. Reviewing the position of this question of the Architects' Education and Registration Bill, and having regard to the fact that other countries are promulgating similar measures, and that adverse critics are becoming more pronounced in their hostility, but less numerous, I am glad to think that the "flowing tide" is with the Bill. The public generally are under the impression that such an Act has been in the Statute Book for generations, and those to whom I have spoken upon the subject expressed astonishment that such is not the case. I trust that in the near future Architectural Art Education will be provided for under the Architects' Education and Registration Act; in the mean time, the question should be discussed with calmness and deliberation befitting the importance of the interests involved.

Mr. SETH-SMITH proposed a cordial vote of thanks to the President for his address, remarking that its lucid exposition of the position of the Architects' Registration question was a good omen for the usefulness of the session. He regarded the world's congress of architects to be held at Chicago next summer as an admirable suggestion likely to bring professional men of many nations into touch with each other; he trusted that the question of registration would be discussed at that gathering. Those who had read the work lately published by the Memorialists must have been struck with the diversity of views held by the writers.

Mr. MARSHALL ROBINSON, of Bolton, seconded the vote of thanks, which was supported by Mr. E. J. HAMILTON, of Brighton, and carried by acclamation.

The President, in reply, said he was amused when he read the Memorialists' book to see how lame in argument and contradictory in statement these pleas were. It was suggestive that thirteen combined to write the essays, and that the outcome was a book which was only gilt at the top, and was crude and rough in all other respects.

THE ANNUAL DINNER.

In the evening the annual dinner was held at the Holborn Restaurant, the President in the chair. Among those present were:—Sir William H. Marling, Mr. L. Atherley-Jones, M.P., Mr. Wyke Bayliss (President of the Royal Society of British Artists), Mr. J. W. Wilson (President of the Society of Engineers), Rev. P. S. O'Brien, D.D., Mr. H. H. Bartlett (President of the Builders' Institute), Mr. W. H. Seth-Smith (past-president), Mr. Edgar Farman (hon. secretary), Mr. E. Day (vice-president), Mr. E. J. Hamilton (vice-president), Mr. H. Adams, M.Inst.C.E., Mr. William Woodward, A.R.I.B.A., Mr. Ellis Marsland, Mr. G. Highton, F.R.I.B.A., Mr. G.

Baines, F.R.I.B.A., Mr. Bassett Hopkins, L.C.C., Mr. W. Allport, F.S.I., Mr. E. J. Kibblewhite, Mr. E. S. Tidman, F.S.I., Mr. R. Cruwys, F.S.I., Mr. Sydney Marsland, and Mr. G. A. T. Middleton (secretary).

The toast of "The Queen" having been duly honoured, the President proposed "The Clergy of all Denominations," to which the Rev. Dr. O'BRIEN responded. Mr. E. J. HAMILTON proposed "The Architects' Registration and Education Bill Committee," remarking that the Bill was especially needed in the provinces. When passed, it was bound to prove beneficial both to the architects and the public. Mr. ATHERLEY-JONES, M.P., said that, as the Member of the House of Commons into whose hands had been confided the honour of looking after the interests of the Bill, he had singular pleasure in replying to the toast. He believed that the Bill had been conceived in no sordid or narrow interest, but that the motive which had actuated its authors was to secure the application of better materials, sounder methods, and more scientific principles in building. The ancient idea of architecture embodied strength, utility, and beauty, and modern practice had added sanitation. It was not necessary that an engineer should be an architect, but it was necessary that an architect should be an engineer; and such was the purport of the Bill. For years past the Legislature had devoted itself to sanitary legislation; yet they were constantly met with complaints about the absurdly inefficient materials and outrageously unscientific methods employed for the purpose of building houses. Therefore the society had come to the conclusion that a Bill should be passed to confer security on the public upon this point. Mr. G. BAINES, F.R.I.B.A., proposed "The Fine Arts." Mr. WYKE BAYLISS, President of the Royal Society of British Artists, replying, said that the poets seemed to know very little about architecture, for they dreamed that they dwelt in marble halls, but it was only a dream, and when they came upon gorgeous palaces and solemn temples these dissolved away, which was the very last thing that an architect would like to occur to his work (laughter). Dante talked about everything else in the world that then existed except architecture; he dismissed Venice as a kind of furnace, and recorded the petty squabbles of Florence, but nothing of its buildings, and the only city he described was in the heart of Hell, where no doubt he thought the architects should be (laughter). With regard to painting, architecture had no better servant nor more terrible master than the painter. When at any time in the history of art the work of the architect had been transferred to the hands of the painter, architecture had been degraded. Perfect architecture depended on the conception of the building being carried out from first to last perfect in itself, into which pictures might be brought, as men and women, sculpture and music would afterwards enter. When Michael Angelo and the other painters of the Renaissance began to build the Italian churches, instantly stucco arose, because it was the best thing to paint on, and they erected buildings for the purpose of making walls to paint their pictures on. He had an infinite regard for sculpture, but our climate was against it, and made its use difficult. But there was one of the loveliest things in the world that we Englishmen could cultivate, and that was the art of wood-carving (cheers). It seemed frightful that this art should not live out its life and be seen in exhibitions as pictures were seen. "The Society of Architects" was proposed by Sir W. H. MARLING, and responded to by the President. Mr. H. ADAMS gave "Science," and Mr. J. W. WILSON replied; Mr. W. L. YOUNG proposed "Architectural Art," and Mr. W. H. SETH-SMITH responded; Mr. ELLIS MARSLAND, "The London County Council," Mr. BASSETT HOPKINS, L.C.C., replying, and Mr. A. STONER, F.S.I., in conclusion, proposed "Architectural Crafts," Mr. H. H. BARTLETT, President of the Builders' Institute, rising in response.

THEATRES.—XII.

By ERNEST A. E. WOODROW, A.R.I.B.A.

IN reading accounts of disasters from fire and panic in theatres, the most harrowing details are found to be those which describe the fearful struggles and blocks occurring on staircases. When people rush madly down the stairs, these

behind pushing those in front, the inevitable consequence is that some must stumble and fall, while others trample on, or fall over them, until a human barrier absolutely fills up the space from wall to wall, and from floor to a height scarcely credible. In the Gateshead disaster, last year, the living and dead lay together in a heap of five deep on the gallery staircase, with a struggling mass of panic-stricken creatures behind them, unable to proceed further on account of the awful mass before them. With these known facts to guide him, and a knowledge that they have occurred, not once or twice, but many times, with what sense of anxiety and responsibility must the architect proceed to design the staircases for any public building! Is it possible to design a staircase in such a manner as to entirely obviate such disasters? It is possible to vastly improve upon the form, construction, and planning of many staircases that have had to do

largely governed by the site and its possibilities. Now I contend that the site *must* be such as to admit of the requisite number of exits—in fact, in London this cannot in any way be overcome.

C

A

duty for the public for years past. There was, in years gone by, too often a tendency to disregard the requirements of the cheaper parts of the house, and the gallery had to content itself with only one staircase—narrow, and with winders at every turn. It is indeed fortunate for us that such a state of things as this is of the past, for it is no longer possible for anyone to construct such death-traps in London for the use of the public.

Before quoting or commenting upon the English and foreign rules and regulations with regard to staircases, I will shortly review the opinions of certain writers of late years on this subject. It will be within the recollection of my readers that Mr. Ralph Nevill dwelt fully upon this question a few years since, in a paper read by him before the Institute of British Architects. Speaking

Speaking specially of staircases, Mr. Nevill remarked that many poems have been sung of late over the supposed happy innovation of straight flights and exits, but that in his opinion "a more frightfully dangerous arrangement" could not possibly be concocted; for how, he asked, would it be possible to stand against the direct pressure of one or two hundred people? "Surely," he said, "no such stairs ought to be licensed, unless it be divided up with a hand-rail to every person . . . this mischievous idea has been advertised as one of the advantages of Mr. Irving's theatre" (see section A B, page 383 of this volume of the BUILDING NEWS).

It is true that long, straight flights are most objectionable and dangerous, and that it is all important to distribute the crowd, and prevent the whole pressure being brought to bear on any one part of the staircase. There should therefore be

C2

intermediate landings to break up the flights, affording persons a chance of resisting the pressure from behind, besides giving a resting-place for those ascending, as well as those descending; in considering the arrangement of staircases, we must not lose sight of the fact that with a sunk pit people have to ascend to reach the street. Facilities for entrance should also not be overlooked while considering the more important part of the question, of facilities for exit. The London County Council recognise an evil in long, straight staircases, and provide against it by insisting that no staircase shall have more than two flights of twelve steps each, without a turn.

To return to Mr. Nevill's paper, in which he pointed out that the ordinary form of stair is the square or oblong, with landings at the ends or corners, "the weak point of this form is that at

B

upon entrances, exits, and staircases, he observed that these subjects were particularly within the architect's province, and that the best form of stairs was especially one that could be "easily grasped." With regard to entrances and exits, they must of necessity be largely governed by the site and its possibilities. There could, said Mr. Nevill, be little difficulty where space could be had all round a theatre, as at that which was then being built by Mr. Phipps in Shaftesbury-avenue, (now known as the Shaftesbury Theatre); he pointed out that Mr. Irving's plan (illustrated in Chapter VII. in the BUILDING NEWS of September 16) not only required a space all round, but two good roads were needed on each side, suitable in capacity and direction for the procession of carriages, and without such roads the plan would collapse. These remarks read as if the writer thought that the exits should be made to conform to any given site, as he says they must be

every landing, whilst the inside man has a very sharp and nasty turn to make, the outside man has a long way to go, and if there is much pressure behind he is projected violently into the

empty space." Anyone ascending a staircase should, he remarked, take the trouble of observing his neighbours, and note their relative positions when they reach the top; he will then be surprised to find how far apart they are scattered. "If such dislocation is possible going upstairs in no particular hurry, what must be the case, in panic, coming downstairs?"

Much has been said from time to time of the various forms which staircases in theatres should take, and I have reproduced here, a series of diagrams, which Mr. Nevill used, to illustrate his views on the matter. The worst form of landing stair, he said, is that shown at A, in which there are only two risers in the centre of the landing. I would point out that the Council's rules will not permit of any new building having staircases with flights of more than twelve steps, or less than three, so this arrangement of two steps at the half-landing would not be allowed. There is

E

certainly great danger of stumbling over steps placed thus unexpectedly at a sharp turn of a staircase. The best form, according to Mr. Nevill—and undoubtedly it is a good one—is that of the Prince of Wales's Theatre gallery staircase, in which four risers in a flight go round a square centre. (Fig. C.) The rounding off of the corners of the square landing by hand-rails is a custom now frequently adopted, as it destroys the corner "pocket," into which the weak may be thrust and held there by the passing crowd. (Fig. C1.) A suggestion comes from the writer whose exhaustive remarks on the subject we are now considering, that a barrier should be put instead of a hand-rail, leaving a space of 15in. in the middle of it, to form a convenient refuge for anyone faint or over-pressed, to enter and regain breath. (Fig. E.) The fear to my mind is that they might be trapped, and unable to get out again, because of the pressure

F

of the crowd; or, on the other hand, people might be forced in against their will, and be prevented from proceeding down the staircase. Mr. Nevill, however, said he would not deliberately build a square corner for this purpose; but if the empty space were there it might be utilised in this manner. It would certainly be put to better use, than by being filled with a pay-box, as is sometimes the case.

With regard to the description of the remaining diagrams, I quote the writer in full:—"The radius of a circular staircase would have to be too large to be practicable; but in an ellipse, as Fig. B, the steps at the sides may be set to a very large radius, and the small ends used as landings. The objection to winders does not, of course, apply to treads of this description. I may point out that the ascent of a staircase on an ample curve is much less fatiguing than that of a square stairs, where one has to make an unpleasant turn at every landing. Old people

D

always complain of this. In our large mansions we have instances of curved plans; but they are unfamiliar to us, as most of our stairs in England are modelled on those constructed of oak, where such an arrangement is not possible. In France, on the contrary, where stone governs design, they are common. The elliptic curve may be applied with equal advantage to the sides of a triangle, or of a square, as in Figs. D, F, and

G

H. One of the chief objections to the square landing may be taken away by treating the flights as in Fig. E—that is, by not carrying the steps so far as the inside corner of the wall.”

Sir Eyre M. Shaw's views upon this particular point, are that stairs with bends at a right or even an acute angle are much safer than straight flights. A uniform movement of persons passing down a staircase is to a certain extent desirable, particularly in a panic. Angles in the stairs interfere with this uniformity to a certain degree, as the persons on the outside of the bends have a greater distance to travel than those on the inside; but the absence of pressure is of greater importance than uniformity of movement, and, consequently, where great crowds have to pass downstairs angles are very useful. “In some buildings, too, it may be possible to construct stairs with angles in alternate directions, first right and then left, and thus, to a certain extent, to combine uniformity of movement with absence of pressure.” Mr. Buckle, speaking of theatre staircases, says that they should be as near as practicable to the point of exit without intervening passages. Their arrangement will exercise the ingenuity of the designer if safety, convenience, and economy are properly considered. Staircases should invariably be wider than the passages or corridors leading to them, the reason being that crowds move less rapidly on the staircases than on the level. This latter remark is

H.

one that the architect should bear in mind, for a staircase, that is fed too rapidly from the auditorium, will be sure to become a source of danger, and be easily blocked.

Mr. Buckle's theory is to abolish staircases and to substitute sloping ways. Even were this not done in the wholesale way advocated in his “Safety Theatre,” it should be adopted in all cases to overcome slight differences of level in the passages. “As to differences of level, it will be found that gradients not exceeding one in ten are perfectly safe for a crowd, and that even the smallest steps are more or less unsafe. Where there is a gradient, however, it is most desirable to avoid any pressure near it, as persons, after entering a gradient downwards, involuntarily attain an increased speed, and if this be further accelerated by a pressure from behind, accidents happen. This danger, however, is easily guarded against,

either by having the entrance to the gradient at a wide angle, from the communicating passages, or by a simple arrangement of barriers at alternate sides, reducing the number of persons in each compartment, so to speak, to about fifty or thereabouts, as this number cannot create a sufficient pressure to do injury.” I quote again from Sir Eyre M. Shaw's “Fires in Theatres.”

Having pointed out the danger of single steps as stumbling-blocks, I have now to draw attention to the objections of irregularities and differences in the rise and tread of steps in staircases. Anyone who comes suddenly and unexpectedly upon a step that is higher or narrower than those over which he has just passed, runs a very great risk of falling, and a fall on a staircase, in a panic, is fatal. A change of “going” from one flight to the next is also most objectionable, for the same reasons. At the best of times it is, to say the least, uncomfortable to have to suddenly change the length of one's stride in ascending or descending a staircase; yet there is often a tendency to vary the rise, or tread, of a flight to work in the staircases to the fixed levels of the corridors; but the dangers are so great that the temptation must never be given way to. The Council demand that the treads of the steps shall be not less than 11 in. wide, and the risers not more than 6 in. high, and that there shall be no winders, but the treads of each flight shall be uniform in width. This rule would throw out of court the elliptical and curved staircases advocated by Mr. Nevill and illustrated above, in spite of his arguments of the additional safety of his plan, and in designing a theatre for London there is no departure from the rules of this municipal body, permitted.

It is universally accepted that winders in a staircase must, under all circumstances, be omitted, on account of their extreme danger. When referring to the foreign rules, we shall find this is enforced in all countries. The question of the width of tread and height of riser must be governed, of course, by the character of the staircase; what is suitable for an East-end gallery is not good enough for an opera house grand staircase; yet no staircase ought to be of poorer dimensions than those insisted upon by the Council. The wider the tread, the shallower the rise, of course, it follows, the better and the safer the staircase for public use.

The importance of the planning of a theatre staircase is so great, and the opinions and rules on the subject so many, I cannot dispose of them in one chapter. I shall, therefore, only refer to one more detail at present, leaving the rest of the question for a future article.

Everyone knows that, on both sides of all staircases and flights of steps, there should be hand-rails for the people to cling on to, to prevent them being thrown over by the pressure from behind. Continuous hand-rails must be fixed on both sides of all steps and landings of a London theatre, and be supported by strong metal brackets built into the wall. The hand-rails must be chased into the walls, where the thickness of walls will permit; but in all cases where the flights of steps return, the newel wall must be chased so as to allow the hand-rail to turn without projecting on the landing or diminishing the available width of the staircase. Many writers have advised dividing hand-rails, and some have advocated that the staircases should be subdivided by several hand-rails from top to bottom, making a series of narrow staircases just wide enough for people to pass out in Indian file. This, indeed, may have its advantages, but great width of staircase would be required. Economy of space almost forbids the adoption of this arrangement. If, however, the staircase is just wide enough for four to go up or down abreast in comfort, those next the wall will find the support from the rail sufficient to allow the two in the centre to lean on them. Sir Eyre M. Shaw writes that in inclosed passages and staircases, hand-rails at a distance of about 3 in. from the walls on both sides are always an advantage. It is true that they occupy some space, and this is against them; but, on the other hand, they almost invariably prevent persons falling down and being trodden on. When a crush comes, the persons at the sides hold on to the rail, and those in the middle hold on to them, and it is most unusual with such an arrangement for anyone to be trodden on, whereas in passages without a rail there is nothing to prevent persons falling, and when they do fall, the consequences are most serious, not only to themselves through being trampled

on, but to all in the vicinity, on account of the obstruction, and the increased impatience or panic which is sure to follow it. A hand-rail has also the advantage of giving those near it something to hold on to, thus enabling them in some measure to regulate the speed, and so diminish some of the worst consequences of a rush. Such is the opinion of one of the greatest authorities in the world on theatre fires.

IRON ARCHES OF LARGE SPAN.—IV.

CAST IRON.

ONE of the principal points of difference between an arch of metal and its prototype of masonry or brick is, that the latter two are regarded as incapable of resisting a bending moment, any action that might arise in this respect due to the tenacious qualities of the mortar or cement in which the voussoirs or bricks of the arch-ring are set being neglected. In a stone arch, each voussoir may be considered theoretically as joined to its neighbours by a hinge, through which the pressure would pass, and if the centres of the hinges coincided with the medial line of the arch, then the true line of resistance would approximate very closely to it. These conditions would probably not apply with the same force to a metallic arch constructed of voussoirs or blocks, of which we gave an example in a former article on this subject, although the principle of construction is the same in both instances. If we were further to assume that each separate segment of a cast-iron arched rib were to represent simply a long voussoir, it might be difficult to determine exactly where the bending action would first take place. If we further suppose that the length of the segments was increased until each was equal to the semi-arch, the case resolves itself into that of a pair of inclined rafters meeting at the apex. This is a far more correct assumption than that of considering an arched rib in the light of an assemblage of separate curvilinear pieces, resting upon two supports. It may be viewed as one single arch or vault constructed of a material susceptible of deflection and deformation, without, within certain limits, endangering the equilibrium of the structure. Actual experiments, of which we shall give a practical example, have proved that when subjected to loads cast-iron arched ribs undergo a flattening at the crown, the general tendency being to shorten the arc and lengthen the chord. The amount of deformation which the normal curve suffers, although it varies with the load, bears no direct proportion to it. In all cases it is very slight, and after experiencing it, the arcs remain nearly circular.

In the “Système Polonceau,” of which we gave, in section and elevation, an example in our last article, we drew attention to the action of the bolts. The halving of the two elliptically-shaped ribs rendered it necessary for the bolts to be continuous along the face of the arch both on the extrados and intrados; but as the whole rib is composed of so many segments of these compound sections, the radial joints in the depth of the rib require bolts through their flanges in common with all segmental cast-iron arched ribs. Face bolts of this description have two functions to fulfil. In the first place, they must make what is termed “a good joint” between the contiguous segments, and must also be strong enough to prevent any overturning of the arch, owing to the action of external transverse forces, the tendency of which is to cause one segment of the rib to slide upon another in the plane of the joint. An iron arch will not fail in the same manner in which the ordinary fracture of a common stone arch takes place. Auday, Coulemb, Poncelet, and other authorities confirm the statement that in the latter instance the arch fails by the voussoirs opening at the soffit of the crown, and at the extrados at two points in the haunches or reins of the arch, one on each side between crown and springings. That face-bolts in the radial joints of an arched rib do not serve for the transmission of pressure is proved by the fact that arches have been “struck,” and remained perfectly sound for some time after erection, without the joint bolts being tightly screwed up, or the threads of the screws evincing an indication of wear. Practical experience confirms, therefore, what has been already stated respecting the action of bolts in butt joints exposed wholly to a strain of compression.

The idea conveyed in the adoption of the elliptically-shaped section is clearly seen to be the attempt to increase the stiffness of the rib at the centre of its depth. Another method of obtaining the same result is shown in the cross-section in Fig. 8, which presents

Fig. 8.

some points of interest. The example is that of the cross-section of the cast-iron arched rib of the railway bridge over the Rhone at Terascon. This structure consists of seven segmental arches, having a span of 197 ft., and a rise of 16½. The total depth of the rib is 5 ft. 6 in., which is large compared with the dimensions of the span, as is generally the case in cross-sections other than those belonging to the equal double-flanged system. The section in Fig. 8 may, however, fairly claim to belong to that form, for we may neglect the small central stiffening flange, as its projection beyond the plane of the face of the rib is barely 2½ in. The width of the upper and lower flanges is 1 ft. 4 in., and taking the available depth for calculation to be the distance between the respective centres of gravity of these two flanges, we have its value equal to about 4 ft. As the weight of an arched rib is directly proportional to its sectional area, the latter should be kept as small as possible, consistent with the strength required. Any excess of area beyond what this requisite demands must be regarded as so much extra dead-weight, which does not only not increase the strength of the structure, but to some extent impairs it, and in addition, augments its cost. It is doubtful whether the two vertical prolongations of the central portion of the rib beyond the upper and lower flanges, shown in Fig. 8, contribute in any appreciable degree to the strength of the section. Presuming that they do, and the small central flange as well, put A to represent the total sectional area of the rib; let d equal its extreme depth from out to out, b equal the breadth of either horizontal flange, b_1 that of the small central flange, and put t for the uniform thickness, which is equal to 2 in. Then

$$A = t [D + 2(b - t) + (b_1 - t)] = 199 \text{ square inches.}$$

We shall compare this area with that of the most recent, and one of the best designed cast-iron arched ribs in England, and also with that of some Continental bridges. We shall adduce this example in a future article, as being like the one under present consideration, a railway bridge, and of almost identically the same span, and also under the same practical conditions of loading.

It will be seen from an inspection of Fig. 9, which represents the skeleton elevation of one half of the rib of the Terascon bridge, that the spandrels of this arch are different, both in

Fig. 9.

design and construction, to those belonging to the Pont du Carrousel, illustrated in our last article. The spandrels in Fig. 9 are of the solid sided or plate type, and consist of a framework composed of vertical standards or pillars placed at a certain distance apart, and the spaces filled in with cast-iron plates or panels, which play a subordinate part in comparison with the standards, in transmitting the weight of the "track" and that of the rolling load to the arch beneath. It by no means follows that the whole duty of the spandrels of an arched rib is restricted to a mere transmission, or transference, of the dead and

live weight over the arch. The manner in which the stresses on the spandrels themselves are effected, will depend in great measure upon their method of attachment, or "articulation," to the rib itself, as well as to the horizontal upper chord, or stringer, belonging to the arch, as will be subsequently pointed out more fully. If the spandrels be rigidly connected to both the rib and the longitudinal chord, as occurs frequently in arches of wrought iron, then the whole may be regarded as one piece of solid framework, and the resistance to a bending moment will be shared in different degrees by each component. There are very few experiments extant, respecting testing to the point of fracture—the only reliable test, after all—either cast or wrought-iron ribs. In all the experiments undertaken with ribs of the former material, the arch failed by the breaking of the metal in the reins or haunches. It should also be noted that the failure always took place before the ultimate crushing strength of the cast-iron was reached. This result must have been due to one of three causes: the haunches or spandrels may have been badly designed, and therefore too weak for their work, or improperly connected to the rib. The metal itself may have been of inferior quality throughout, and in addition, the form or cross-section of the rib, as is very probable, was not that which theory and experience have since pronounced to be the correct one for constructions of this description. In stating that the spandrels may have been too weak, it must not be taken for granted that they were not strong enough to do their own share of the work, for they might have been too weak to resist the stress brought upon them by the deformation of the rib itself. The latter also, owing to imperfect designing, would likewise be subject to more deformation than would be the case with a properly proportioned section.

CARPENTRY AND JOINERY.—XLVI.

WAINSCOTING (continued).

WAINSCOTING containing panels reaching from bottom rail to top rail have been dealt with—that is, one panel in height only; but it will be readily seen that this would suit only wainscoting of a very limited height, unless variety were obtained by planting a surface moulding upon the panel, and thus working out a number of fancy geometric designs which would give a necessary variety.

Fig. 303 gives a few outlines suitable to work to, in order to take away the plainness. For the carrying out of these designs, one important consideration is required—namely, that the moulding planted round the framing be such as that the moulding forming the geometric design will mitre into its members, or, at least, some portion of them.

Fig. 304 gives three examples of mouldings suitable for the purpose. On the left-hand side is the moulding in full, and on the right side is the portion of the moulding which is used to form the geometric figure upon the panel. A dotted line is shown on the full-sized moulding to show to what point the other moulding will mitre, and also that the same dotted line divides the surface moulding in two. The three examples given will enable the reader to know just exactly what kind of moulding will be suitable for the purpose stated. It needs hardly be said that these little mouldings are mitred carefully to the design which may be marked upon the panel; they are then glued and bradded (sprigged) to. Of course, if it is only for painted work, it may do to dispense with glueing; but, if in hard wood, these mouldings must be put to with needle-points. In mitring, a bevel-edged chisel will be found very handy.

Where it can be used, a mitre-plane comes in useful for this class of work. It will be seen that the first moulding shown in Fig. 304 is a moulding which may be wrought upon the solid, and therefore very suitable for oak and other hard woods. If any of these are used, as has been previously stated, they should be put on with needle-points—or, better still, a fine line may be drawn on each side of the moulding to mark its place, and then the panel bored for screws, and the moulding screwed to, a little glue being previously put upon the back of the moulding. It will be readily seen that these designs can be wrought upon any panel-work, and that they are not confined to wainscoting only.

Passing on from wainscoting having only one panel in its height, and allowing the reader to treat it in any of the methods suggested, or to develop a new one which may occur to him

Fig. 303.

through any suggestion here given, we come naturally to wainscoting two panels in height, and then the question arises, How should they be divided?

Fig. 305 gives two elevations to solve the problem, one being only a skeleton. In the one case a square panel is arranged at the top, and the bottom panel is such as the height of the

Fig. 304.

framing will allow. In the other example, that in skeleton outline, what is termed a *lying* panel extending over two lower panels is adopted. In both these cases every other muntin should run through—in the skeleton one it is necessary, also in the other one for sake of the framing to hold it well together. It will be found in practice

that the alternative muntins going through in this way, and the intermediate rail being broken up, it is easy to keep the framing straight; but if it is attempted to run the intermediate rail all the length, the framing will not wedge up without a great deal of trouble and the use of

Fig. 305.

pins or screws to assist. The screws would be put in from the back side, not extending through; and the same may be said of the pins, although often they are bored for and driven from the front. These alternative muntins should be mortised through both top and bottom rails. This style of wainscoting may be much improved by the use of raised panels, such as have been described for entrance doors. One of the simplest

Fig. 306.

and most effective panels of this class for wainscoting is shown in Fig. 306.

The first thing noticed in the figure is the moulding, which is composed of a fillet, scotia, and bead, and this moulding is worked on the solid. The ploughing or grooving for the panel is made of the size shown, so as to allow sufficient strength at the back.

The panel is next noticed, and how simple the raising is, showing a sunk face and margin from the bead. This margin should be equal; a little care in the rebating to fit the plough groove will make this all right, providing the panel is made correctly to the size. Supposing there is a looseness in the panel, and the margin not correct on that account, adjust it, and then put one or two needle-points in through the bead, and this will keep it stationary.

Supposing wainscoting such as shown in Fig. 306 were to be made of oak, then, as stated in connection with Fig. 305, the alternative muntins would be put through for ease in wedging, and also it is easier to pare out a mortise when it is through, as considerable time is occupied in getting out the core, and the tenons must be the proper length, or even a little shorter, so as that the shoulders will bear rather than

the tenon. When all things are taken into consideration, it is the readier method to mortise through. There is no comparison in wedging up, as these alternative muntins divide the framing into equal portions, each of which may be said to be self-contained; all that is required being to have the cross, or horizontal pieces, sufficiently long to keep all shoulders close joints.

Fig. 307 gives a moulding suitable for the base

Fig. 307.

or skirting of this wainscoting. It is advisable to rebate the wainscoting a little, so as to suit this; that is, the bottom rail should show a little more than the top one, and be rebated from this point downwards—say $\frac{1}{4}$ in. deep. The object of this is that when the skirting is put on, and, if a shrinkage occurs, the spectator does not look directly down upon it; but must stand off, and even stoop, unless he is a good way off, to see the trace of shrinkage.

Fig. 308 shows a moulding suitable for a capping to the wainscoting. This is taken from actual work, and no difficulty should present itself in putting it on, as it is nailed to the ground, and may be nailed a little to the framing also. Of course, in a hall, and with a wainscoting 4ft. 6in. or 5ft. in height, a more massive skirting may be required, and in such case there may be, in addition to the base moulding, a plinth (double faced) corresponding somewhat with the skirting, as shown in former figures, say Figs. 294 and 295. The capping and base should be scribed where possible, and also the moulding of the framing shown in Fig. 306. The moulding spoken of

Fig. 308.

can only have its scotia scribed, as the bead, being a return one, requires mitring. This will cause a slight complication; but these points, with a little care on the part of the workman, will enable him to carry it out satisfactorily.

The writer has found the readiest method for this class of work is to have a little pattern of one of the stiles or muntins, and use this in setting the mortise gauge, which will enable the workman to see how far he can bring his mortise forward, and then when tenoning and mortising is done and all ready for fitting and scribing, put each tenon into its respective mortise, and mark the bead where the two beads meet, and then mitre and scribe accordingly.

A. C. SKILLING.

BRICKS AND JOINTS IN BRICKWORK.

—II.

BEFORE dismissing the subject Fletton bricks *versus* London stocks, it is well, perhaps, to remark that the inferior Fletton bricks are pale backed, and in appearance a pale whitish-red colour. Some of these bricks when struck with the brick-trowel, in the act of reducing the brick to a bat or three-quarter brick, shiver to pieces, an evidence of the want of cohesion in the body of the brick, due to the refractory nature of the clay, combined with insufficient pugging and firing. Fletton bricks might be theoretically objected to as a backing to London stock-facings on account of the difference in thickness of the two kinds of bricks—stocks requiring $\frac{3}{4}$ in. bed-joints and Flettons $\frac{1}{2}$ in. bed-joints to make the brickwork rise vertically four courses to a foot. The strength of a wall depends so much upon the quality of the mortar used that, though faced with stocks on one side and Flettons on the other, yet, under certain conditions, it may be practically as sound as a wall built wholly of one class of bricks. In first-class mortar the ingredients are clean, sharp sand (silex) and lime in the usually prescribed proportion—viz., three measures of sand to one measure of greystone lime; or, two measures of sand to one measure of blue Lias lime, which will yield or shrink very little, if any, in the process of drying. The reason of this is to be found in the fact that the proportions are such that the lime when slaked has no great excess over the quantity required to fill the interstices between the angular grains of sand, driven closely together in the act of laying the brick. The mortar being thus closely compacted, no appreciable shrinkage takes place. The same cannot be said of bad mortar, or even otherwise good mortar, which has been overground in a mortar-mill to such a degree of fineness that the angularity or body of the sand has been eliminated.

The general make and uneven beds of London stocks require $\frac{3}{4}$ in. bed-joints to make satisfactory work, both with respect to soundness and appearance. The Fletton bricks, on the other hand, having true and regular beds, admit of $\frac{1}{2}$ in. bed-joints. There could not, perhaps, be any better practical test of the comparative merits of the bricks in question as building material than that which would be afforded by pulling down two walls of long standing which had been well built under exactly the same conditions—one with Flettons, the other with stocks. In the case of the stocks it would be found (a consequence of their ability to knit together in the mass) that the fracture occasioned by pulling the work to pieces would often take place through the body of the hard stocks, while the Flettons, with their well-finished faces, affording less adhesion for the mortar, would separate and leave the mortar-joints much more readily than in the case of stocks.

In the choice of bricks, those having a "frog" on one of the beds are to be preferred (all other conditions being equal) to those without a frog. The bed in which the frog is formed distinguishes that as the upper bed of the brick. The upper bed in hand-made stocks is generally found to be slightly longer than the bottom bed, to admit of the brick in the clay state leaving the mould, which, to some extent, accounts for the bevelled headers or ends of the bricks. Such bricks when abnormally bevelled cannot possibly be laid in any other way than frog upwards, which, if departed from, would cause the lower edge of the brick to project, to the extent of its bevel, beyond the face of the lower brick upon which it was laid; the upper edge of the brick in all cases, sailing courses excepted, being laid to the brick-layer's line. In sailing courses the lower edge of the brick is laid to the line. When the ends of the bricks are much bevelled, the bricklayer finds it necessary to snap the bricks in two, and bed the snap-headers transversely out of level, or dipping into the wall, so as to bring the end of the brick into the same vertical plane as the brickwork below it—a practice admissible only to a very small extent. The original intention of the frog was to drive the clay well into the brick mould, and to form a dowel for every brick when laid in the wall. In some of the heavier and more costly kinds of bricks, made at a considerable distance from London, this idea is taken advantage of for the double purpose of economising the clay and reducing the cost of freightage, by making the bricks with a deep frog on both beds of the bricks. In estimating for work with bricks of this kind it should be borne in mind

that more mortar will be required for a given piece of brickwork than if executed with bricks having one frog only. The writer has noticed this peculiarity more in glazed bricks than in any other kind. In such instances (on account of the smallness of joints in glazed work) it is well to have the frog in the bottom bed of the brick filled in by the bricklayer immediately before laying it on its mortar bed, to obviate the possibility of flushing the glaze by the superincumbent weight being thrown on the outer edges, instead of upon the whole area of the brick. A brick having a frog admits of closer and sounder bedding than a brick having no frog, unless special precautions be taken in well soaking the latter brick and bedding it in fine mortar, a course not usually pursued unless under strict supervision. Makers of glazed bricks seem to have an idea the joints cannot be kept too close, the bricks admitting in some instances of not more than $\frac{1}{16}$ in. bed-joints. The idea, though true in principle, is unsound in practice, as neither sound nor satisfactory work—as far as appearance goes—can be made with such very fine joints. The joints should not be less than $\frac{1}{8}$ in., and not more than $\frac{1}{4}$ in.; and even then it would at times be found necessary to sort or gauge the bricks to an even thickness before laying them, owing to an unequal shrinkage of the clay in firing. The bed-joints are sometimes regulated to a uniform width by the bricklayer, after the work is built, by cutting off the irregularities with a hammer and boaster (a broad-bladed chisel about 5 in. wide), a practice which should, if possible, be avoided, for fear of flushing the glaze. In selecting glazed bricks it is advisable never to be wholly guided by sample bricks, but rather to examine them in some piece of work previously built, and which has stood some little time, carefully noting if craze or other defect be present in the glaze. The craze, in appearance, is somewhat like the crackle in china. John Sparkes, director of the Lambeth School of Art, in describing glazed ware, says: "To make this were perfectly able to withstand the effects of atmospheric attack, two points are necessary to be attended to. One is that the body and the glaze shall be so perfectly fitted for each other that there shall be no uneven and different contraction. Crazing, as it is called, on glazed ware is the effect of two materials that do not pull together, so to speak, and is to be avoided." Glazed bricks are divided into dip glazed and salt glazed. The latter are a brown colour, peculiar to salt-glazed ware, and though sometimes mottled in appearance, due to the salt and other causes, possess an almost imperishable glaze, and are therefore peculiarly well suited for exterior street dados, and where subject to rough usage. The salt glaze "is fired and glazed in one operation. During the first firing, which converts the brittle and useless clay into impervious ware, when an intense white heat is reached, salt is thrown into the salt-glazing kiln either from above, through holes in the crown of the kiln, or into the fire-holes, or both. The intense heat decomposes the salt, which is changed into a gaseous fume or steam. One constituent of the salt, the chlorine, escapes out of the kiln as vapour. Another portion, however, the soda, as it flies through the kiln, meets the white-hot ware, in which is always a portion of siliceous or flint, and forms with it a silicate of soda, or soda-glass." The dip-glazed bricks, previously fired, are first coated with a fine white clay in slip form to cover the rough body of the bricks, and as a medium to receive the glazing material. The clay used to form this coating or slip is mostly Staffordshire china clay. The dip-glaze sometimes parts from the body of the brick, but the salt-glaze always remains immovably a part of the brick.

F. WALKER.

THE SURVEYORS' INSTITUTION.

THE opening meeting of this society was held at 12, Great George-street, Westminster, on Monday evening last, when the President (Mr. C. J. Shoppee) delivered the customary address to a large and representative gathering of members. After expressing his gratification at the distinction conferred upon him by the members in placing him in the proud but responsible position which he occupied, Mr. Shoppee proceeded, as an urban surveyor, to disclaim any wish or pretension to deal authoritatively with subjects which affected only the agricultural branch of the surveyors' profession; and, coming to a subject eminently within his own line of practice, dealt, in a few well-chosen and weighty

words, with the report of the Town Holdings Committee. The subjects of reference to that committee he classed under three general heads—(1) Leasehold enfranchisement; (2) the direct assessment of ground rents, and of increased values imparted to land by building operations; and (3) the taxation of vacant building land. The committee had come to the conclusion that leasehold enfranchisement would not, on the whole, have much practical effect in improving the quality of houses built. They were also not convinced that the power of enfranchisement would be generally taken advantage of, especially if coupled, "as must in fairness be the case," with provision to secure to the reversioner the value of his property, and compensate him for the injury inflicted. The direct assessment of ground rents and of improved land values arising from building operations were dealt with in the committee's final report. "The idea," said they, "that ground rents are a class of property that at present escapes assessment for local taxation is, of course, erroneous. The basis of all rating is the whole annual value of the building and the ground on which it stands, regarded as one entire property." The committee came to the conclusion that the ground landlord bears the burden of all rates current at the time he leases the land; but that fresh rates imposed during the run of the lease fall on the lessee. The proposal to lay an additional tax on freeholds was rejected as impracticable, on the ground that the only proper subject of valuation is the ground with the house upon it. The division of rates between landlord and occupier would, in the case of compound householders and of tenants for short terms, be only an apparent advantage to the occupier, and the committee were, of course, averse to any interference with existing contracts. As to the proposal to rate building land, it was not always easy to say when land was ripe for building, and it might be left to the intelligence and self-interest of owners to so manage their property as to get the maximum of income from it, which income was itself taxed.

The President strongly urged upon the Government the necessity of some more stringent provisions for the inspection and control of the building societies, and of a regulation which should compel them to employ a competent person to value the property, which was the security for the depositors' money. The Council of the Institution had, in common with other bodies interested in the laws relating to building in the Metropolis, considered the proposals of the Local Government Board for a codification of the existing Building Acts, and had, after careful consideration, been able to recommend several important modifications of the Government Draft Bill.

The next portion of the address dwelt in an able manner with the suggestions and proposals of the London County Council for the new street which was to connect North and South London. After setting forth the objects which such a street should endeavour to accomplish, the President somewhat severely criticised the position assigned to the Strand end of the great thoroughfare, even as modified in the County Council's latest proposals. It would, he said, concentrate in the least suitable part of the Strand the immense traffic which now found its way by a multitude of routes, and would render the confusion and inconvenience worse, if possible, than it is at present. As an alternative scheme he proposed a street from the Embankment end straight to the western side of Lincoln's Inn-fields, thence trending north-westward to the north end of Little Queen-street, Holborn. This street would run on a level from the Embankment to the Strand, at a depth of some 23 ft. below that thoroughfare, which would cross it by means of a viaduct, and thence for some 1,300 ft. at an easy gradient to Lincoln's Inn-fields, with a spur street on the site of Clare-street, Blackmore-street, and White Hart-street for the Waterloo Bridge traffic. The streets crossed or interfered with were unimportant, and the area one much requiring to be opened up. The idea certainly seems a feasible one, and one which should recommend itself to the very careful consideration of the County Council.

The President next dealt with the Cromwell-road scheme, and the novel fiscal proposals embodied in the Bill for authorising it. Why, he said, should the owner be called upon to pay one-half of the supposed improved value of his premises? Why not all, if the improvement

arose from the action of the County Council alone? He suggested that a clause should empower any owner who wished to do so to sell his property compulsorily to the County Council, who would thus reap the whole instead of a moiety of the improved value. He ridiculed the provision by which the owner was prohibited from contracting himself out of his liabilities. How was this to be done at the end of a lease, unless ground values could be fixed, once and for all; and would the position of the leaseholder be a happy one who found himself, on wishing to renew his lease, with a fresh burden on his shoulders? The proposals were impracticable, and in that they tended to disturb the security of income from land, on which so many small capitalists depended, they were also mischievous.

The new plan for doing away with a "middle-man," in the shape of a contractor, was next touched on, and the speaker pointed out that the contractor had been evolved and continued to exist simply because clients, both public and private, found that the system paid them to adopt. There was never anything to prevent an owner from dispensing with the contractor's services, but the accumulated experience of years had convinced everyone that he performed useful functions, and he had therefore been employed.

Under the new proposals, who was to be responsible for bad work? The individual workmen, or the County Council, as the rate-payers' middleman, responsible pecuniarily to no one? The address then dealt with the strides made in the direction of sanitary science, and especially with the Plumbers' Registration Bill, and, at greater length than our space permits us to quote in full, with the London Water Question.

The Small Holdings Acts and their operation, the depression of agriculture, the redemption of tithe-rent charge, and the movement for technical and secondary education were all treated of in an exhaustive manner, and the address closed with a suitable reference to the great success of the system of examinations founded some ten years ago by the Institution, and since immensely extended.

Sir R. E. Webster, Q.C., M.P. (associate of council), having moved a vote of thanks to Mr. Shoppee for his address, and the motion having been seconded by Mr. R. C. Driver (past-president), and carried unanimously, the meeting adjourned.

CHIPS.

The Torrington Town Council have elected as mayor Mr. Councillor Grant. He is a large employer of labour. Starting life as a carpenter, he is now one of the largest builders and principal houseowners in the district.

The London County Council have appointed Mr. J. J. Sexby as chief officer of the Parks and Open Spaces sub-department, at a salary of £500 a year.

The Almondsbury Hospital and Institute, erected by Mr. Sholto V. Hare as a memorial to his late wife, was opened on Wednesday by the Duchess of Rutland. The building is L shaped on plan, and modernised Queen Anne in style, and is built of Cattybrook brick, with freestone facings. The main entrance is under the clock tower, and leads into a vestibule, from which access is gained to the parish room, the dispensary, the coffee bar, the domestic offices, and the main staircase. On the first floor are a large hall, six bedrooms, and a committee-room.

The proposal of the Head Master of Winchester College to build a new chapel in celebration of the five hundredth anniversary of the founding of the school in 1393 having been conclusively negatived by the Old Wykehamists, it has now been decided to reset the old chapel and to erect in it a western gallery. The architect is Mr. J. T. Micklethwaite, F.S.A.

The Burton-on-Trent town council have decided to apply for permission to borrow £11,500 for the erection of an infectious diseases hospital, and £80,000 in respect of the sewerage and electric-light schemes.

A new organ, built by Messrs. Abbott and Smith, of Leeds, was opened on Sunday at Meanwood Church, near Leeds. It is built on a new system of electric control, and can be played from any position in the church. It contains 30 stops and 1,400 pipes, and is placed in an oak case with polished pipes.

Mr. Passmore Edwards has, says the London correspondent of the *Manchester Guardian*, intimated his willingness to give £1,000 for the purpose of erecting a drinking fountain as a memorial of Mr. James Beal and Mr. J. F. B. Firth, the pioneers of London municipal reform.

ST. GEORGE, HANOVER SQUARE, PUBLIC LIBRARY.

THIS design was recently selected in a limited competition, and the building is now in course of erection in the Buckingham Palace-road, on a site presented to the parish by his Grace the Duke of Westminster. As will be seen from the plan streets on both frontages exist, and on both sides there are buildings which preclude the possibility of obtaining light by windows on either side. The requirements being that all the principal rooms should be on the ground floor the course adopted was to occupy the whole area, and provide top lights to some of the rooms in lieu of providing areas for light, which, as a rule, are of little service unless they are of sufficient size to allow the admission of the rays of sunlight at about 45°. Another requirement was the economical supervision of the staff by the librarian. This was solved by placing the librarian's office in the centre of the building, with the various offices grouped around, thereby giving easy supervision of the several departments, as well as the entrance hall, staircase, and exits. On the first floor (over the front portion only) is a museum and board-room, and the librarian's residence is above, on the second floor, with separate entrance from the Buckingham Palace-road. The façade next the Buckingham Palace-road is to be executed in red gauged brickwork, with Ketton stone dressings. The general contractor for the work is Mr. J. T. Chappell. The architect of the building is Mr. Albert John Bolton, and the drawing from which the illustration is taken was exhibited in the Royal Academy this year.

PAVILION, PALMER PARK, READING.

OUR illustration of the Pavilion, Palmer Park, Reading, is taken from the little view of this building which was exhibited at the Royal Academy during the present year. It forms part of the munificent gift of Mr. George Palmer to the Borough of Reading, known as Palmer Park, and, as will be seen by the plan accompanying the sketch, consists of caretaker's house, refreshment rooms, &c., and conveniences for ladies and gentlemen. The whole of these are well furnished and fitted, and in every trade the work is of the best, all the timber work being of solid oak. Mr. Margetts, of Reading, is the contractor for the building, which was designed by Mr. Ravenscroft, of the same town.

INTERMEDIATE AND TECHNICAL SCHOOL, PORT
TALBOT, GLAMORGANSHIRE.

THIS design was submitted in a recent competition which created a considerable amount of discussion locally. A number of these schools are now being built, or contemplated, under the

Welsh Intermediate Education Act. The building is designed to accord with the desire expressed for a mullioned style, and for realisation in the exceptionally fine-toned local sandstone. The author is Mr. W. L. Griffiths, architect.

A CANADIAN SUMMER COTTAGE.

THE design of this cottage was submitted originally in one of the Toronto Architectural Sketch Club's monthly competitions in 1890. The cottage is to have stone foundations, to be timber-framed, boarded outside, and shingled with white pine shingles left untouched to turn green with exposure to weather. The house is to be lathed and plastered inside. The internal finishings are of white pine varnished. The spacious verandahs are to be noted as being a necessity in the bright sunlight of Canadian summer. Mr. Ernest Wilby, of Temple-avenue, is the architect.

BILLIARD ROOM, FOXOAK, BURHILL, SURREY.

THIS additional room to the house (which we have already illustrated in the BUILDING NEWS for April 22, 1887), was finished soon after last Easter. Messrs. Walter Holt and Son, of Croydon, were the builders. The floor and ceiling-beams are oak, stained green, and the intention is to lessen the prominence of the ungraded green of the billiard table cloth by floating it into the surrounding green of the curtains, ceiling, and tiles. The room, when finally complete, will be a green and gold room—the walls to have a gold paper, and the plaster of the ceiling treated with gold. The tiles to the curved recess are from Messrs. De Morgan and Co., with a fine sea-piece (also in tiles) over the fireplace. The mantelshelf, &c., is of statuary marble. Mr. Hal'sey Ricardo is the architect.

SOUTHDOWN SUSSEX SKETCHES.

LEOMINSTER (*vulgo* "Limster"), near Arundel, in ancient times known as Lolinminster, and sometimes Nonnemister, is now a very unimportant place. To the architect the chief point of interest in the church now consists in the very unusual timber framings which occur in the aisle on the north side of the nave, and are placed against each of the four columns of the arcade. Whether they actually formed part of the original roof or not may be open to question, but it is clear that they are ancient, and for some reason not very evident were designed to carry the roof independent of the arches dividing the aisle off from the main building. The accompanying sketches show both inside and outside of the church, with its long uninterrupted breadth of roof in one slope. The interior view is taken half-way up the nave, in front of the porch door, which is on the north side. At the east end of the aisle is placed the font in a sort of baptistery chapel, beyond which is the priest's door leading into the *quasi* aisle opening into the vestry, which looks outside somewhat like a choir transept. *Wiston Place*.—This house, near Steyning, was erected in the days of Elizabeth by Sir Thomas Sherley, one of the honourable line of Sherley of Wiston, "a family not needing hyperboles." The mansion, like Hardwick Hall, is open to the description of being more glass than wall, particularly on the entrance front. It possesses a very handsome hall, a cube of 40ft., and is covered with an open timber roof. Over the screen at the entrance end of the hall is a gallery leading into the room over the porch, and the big windows seen in our sketch run up the whole height. The residence has been reduced in size, but is still rightly reckoned among the mansions of Sussex, which is not rich in big old houses. The dining-room retains much of the ancient oak carving, dated 1576. *Hurstmonceux Castle*.—The last of the four sketches shows Sir Roger de Wyne's costly castle near Eastbourne, which is one of the earliest brick buildings in England, and when in its complete state was one of the largest private houses in the kingdom. It cost no less than £3,300, which in 1440, the date of its erection, was a very large amount. It is a grand old house even in its ruined condition, with a splendid old garden at the rear. It is surrounded by a moat, now dry, and is quadrangular in form, and has a striking gatehouse.

GLOUCESTER MANSIONS, CAMBRIDGE CIRCUS, W.

THIS building stands on a prominent corner site, facing the new English Opera House, and is so constructed that the ground floor and basement can be let for business purposes as a whole or divided, and the other floors consist each of two self-contained residential flats, which are clearly

shown on the plan attached. There are hydraulic passenger elevators to all floors. The elevation is in Bath stone and red bricks, and the work was carried out under the superintendence and from the designs of the architects, Messrs. Martin and Purchase, of 11, Queen Victoria-street, E.C.

NICHOLASTON PARISH CHURCH, GLAMORGANSHIRE.

THIS illustration represents the east end and reredos of the above church. The reredos is executed in pink alabaster, with pale Irish green marble columns. The figures are carved in white lias, with gold mosaic background. The inner arch and jambs of the east window will also be in alabaster, with Irish green marble shafts. The north and south chancel windows will be executed in similar materials, and the rest of the church windows in green Bridgend stone, with marble columns. The steps leading to the altar are of polished white statuary, Brèche sanguinaire and Belgian black marble consecutively. The entire church will be paved with black and white marble. The work is being executed by Mr. W. Clarke, sculptor, Llandaff, from the designs and under the superintendence of Messrs. Halliday and Anderson, architects, of Cardiff and Llandaff. The choir angel cornice was illustrated by us on April 15, 1892.

PUBLIC BATHS, ASTON.

THE water for supplying these baths is obtained from an artesian well 400ft. deep on the premises. The pumping engine is also utilised for supplying power to generate the electricity with which the whole of the baths are lighted; also a cable is laid to the public buildings and offices, half a mile distant, and these are lighted by electricity from the same source, gas being entirely dispensed with. The water is heated by live steam, supplied from a Lancashire steam boiler, 24ft. long by 7ft. diameter. A duplicate boiler is also provided. The water can be readily heated to 75°. Had the water been heated by the ordinary hot water circulating system, it would have taken five boilers to do the work which is now being done by one. Provision has also been made for the boilers to be readily removed and taken out at any time without materially interfering with anything. The electrical installation is a decided success, and cost £1,600; the cost of the baths, buildings, and engineering is £13,400; total cost, £15,000. Mr. W. A. Davies, Assoc. M. Inst. C.E., the surveyor to the board, is the architect of the work, the plan of which is herewith given.

CHIPS.

The local board of Hampton Wick have raised the salary of Mr. Kemp, their surveyor, from £175 to £200 a year.

The parishioners of Byfleet have just erected a lych-gate as a memorial of the late Rev. Newton John Spicer, who was rector from 1851 to 1884. The lych-gate was designed by Mr. Woodyer, of Grafton.

The tender of Messrs. Reed, Blight, and Co., contractors, Westminster, has been accepted by the Directors of the Clacton-on-Sea Pier and Pavilion Co. for the erection of the new pavilion and sundry other works at their pier. The engineers are Messrs. Kinnipie and Jaffrey, M.M.I.C.E., 3, Victoria-street, London, S.W.

Mr. William Joseph Shayer, the landscape and animal painter, who died at Twickenham last week, aged 81, was the eldest son of Shayer, a better-known landscape painter, whose rural and seaside scenes are highly prized, and who died only a few years ago in his 100th year. The younger Shayer made his reputation by his sporting pictures—hunting, shooting, racing, fishing, and coaching.

Two landscapes, attributed to John Constable, R.A., which have been presented to the Liverpool permanent collection by Mr. Malcolm Guthrie, have been placed in the Rossetti room of the Walker Art Gallery. The first, measuring 5ft. by 3ft., represents "A Summer Storm." The lock gates of a river—probably the Stour—are shown, while overhead are large, gusty rain clouds. On the left of the picture are two canal horses and a labourer. The second canvas portrays "A Rainy Day." Lock gates are also a prominent feature in the landscape, while overhead are rain-clouds, and in the distance trees are seen through the haze.

The latest addition to the National Gallery is a fruit and flower piece by Jan Van Os (1744-1808). It is numbered 1380, and is hung in the Octagon Room. Another work by the same artist, called "Fruit, Flowers, and Dead Birds," is in the Wynn-Ellis collection, and is numbered 1015.

WAYSIDE NOTES.

MR. ROBERT WALKER'S presidential address to the Society of Architects was completely successful. Excellent was the reiteration of the necessity for more thorough architectural education; inspiring, the picturesque allusions to the poetry of architecture; while the telling broadsides against super-sentimentalism displayed many weak points in the battalion of Essays. Mr. Walker makes a most admirable president.

The hearty laughter that greeted these sorties formed a most agreeable prelude to the capital dinner in the evening at the Holborn Restaurant, when, covers being laid for some sixty guests, officers, members, and friends had a thoroughly convivial time under Mr. Walker's genial presidency. The post-prandial, oratorical deliverances were of a high order. Mr. Atherley-Jones, M.P., who has the Registration Bill in his care in the House of Commons, gave proofs of his devotion to the cause in his own clear-headed, far-seeing manner; and Mr. Wyke Bayliss, F.S.A., in responding to the toast of "The Fine Arts," spoke of the relations between painter and architect in his usual earnest, inspiring style. I listened with much interest to the remarks of Sir William Marling, his views of the requirements of modern architecture from a client's standpoint strengthening my old belief that it is to the outside critic, and not to the professional, running in grooves and ruts, that we must look for knight-errants against dogged conservatism in ways and means.

There is, I believe, a prosperous season before the Society of Architects. Its aims, as heretofore, will be distinctly practical; and its lectures, as heretofore, confessedly dealing with architecture as a living progressive art. While the Society continues in this path, it cannot but go forward, both in intrinsic merit and in numbers; for all architects recognise the desirability of keeping architecture abreast of the times, and in the long run will support such institutions as assist this end.

I am very glad to see that Mr. Tate has, through Sir William Harcourt, the present Chancellor of the Exchequer, renewed his generous offer to the nation. It is believed that the offer will be accepted within the next few weeks, and that the difficulty of site has been almost surmounted, Westminster being the probable location of the pictures. This is excellent news, and if the present Government carry the matter through well, it will have done much to earn the respect of not an insignificant section of the public, who will make comparisons between its action and that of its predecessors.

"Tower or no tower?" that was the question. What must have been one of the most diverting discussions at the meetings of the School Board took place on Thursday last; a proposal having been made to erect a tower in connection with the extension of offices now approaching completion, members more or less vigorously declaring for or against the structure. The argument being that the offices as extended form, altogether, a rather drawn-out architectural composition, a central, dominant object was required "to give unity to the building," as the Rev. J. J. Coxhead very truly remarked—if we accept his position on general principles. The estimated cost of the tower is £3,000, and many members, like Mr. Winnett, were "filled with awe at the effect that this tower would have upon the rate-payers." Others, like Canon Bristow, regarded the expenditure as equivalent to "a ha'porth of tar." Some, like genial Mr. John Lobb, were all for the tower; others held with Mr. Huggett, that a tower and a rate of one shilling in the pound were not things of accord. If I may put forward my own idea, it is that the tower would be useless artistically, and only worth its salt as regards the practical accommodation it might afford. Close to the building the tower would not be seen, or at least be of little or no value as a factor in the composition; and when we see these Embankment buildings at a distance there is quite a galaxy of towers, spires, and turrets breaking the general sky-line, and giving themselves away, so to speak, for the benefit of such forlorn buildings as have no towers of their own. In any case, I pray that the Board save us the infliction of another clock in the neighbourhood!

The £3,000 therefore, might well be kept for general educational purposes, and not for illustrations of architectural design. A little of the money might be expended on making some of the schools—being necessary buildings—more presentable. I see a new building near the railway somewhere this side of New Cross, and it is a barbarous object. As I note the magic initials L.S.B. lovingly entwined in a gable, I may be pardoned if I am in error in imagining it to have been erected by the Board.

The St. Pancras competition will attract a large number of competitors. Municipal buildings being a favourite subject, and requiring less previous study and special experience than others, the rank and file of the army of competing architects will enter the arena; and as no entrance fee is demanded, the hard-working and clever, but poor, student has here a decided opportunity to show what in him lies in the way of ability in architectural composition and sound planning. I see that the first premium is arranged on the "merging" principle, which, as Mr. William Young said the other evening in his lecture to the Association, and as I have all along urged, makes it no premium at all. In this particular case it is exceptionally desirable that the successful architect should receive something a little over the 5 per cent. commission. Besides the risk and uncertainty that attends every competition, I see that the inaugurators of this competition stipulate that if a tender is not obtained within 5 per cent. of the sum of £30,000—a sum including, in a very objectionable way, the architect's commission—they will not be liable to the architect for any of his time and trouble in preparing plans, &c., and obtaining a tender. Here we see how the honest have often to suffer for the misdeeds of the unscrupulous. The object of this stipulation is, of course, to prevent dishonest persons endeavouring to gain the competition by submitting designs that will cost more than the amount provided. So far, so good; but it is hard that those who would endeavour honestly to provide a building should have this additional incubus, and by mere accident or oversight run the risk of doing a vast amount of work for nothing. Still, most probably the bulk of competitors will agree that the stipulation as it stands is good, and that the benefits far outweigh the disadvantages. As to the merging of the first premium, this is a meanness scarcely worthy of a large and important London vestry.

How irrepressible is the old Adam in this matter of stipulated cost may be gathered from the curious result of the Bexhill-on-Sea competition. Here all the competitors but two have "outrun the constable," and these two have failed to comply with other conditions. The assessor has recommended the Bexhill local board to increase the proposed outlay from £3,300 to £4,500, and inquired of the competitors whether they will stand their chance with their original design, or prepare an alternative set of plans. If there be another competition, I should advise all not to rest on their oars, but to see how they can improve their designs. We know how a competitor will get it into his head that his design is unimprovable perfection itself; but a word to the wise may be heeded. Of course, a proper and sufficient time should be allowed for the new designs.

From a recent very interesting article in the *Daily Telegraph* on "The Value of City Property," I learn that "some speculators, in their anxiety to make the land carry as heavy a financial load as possible, have been so 'greedy'—to borrow the term used by one agent—as to erect buildings which will not let freely at high rents, simply because the architect has cramped the passages, and robbed the rooms of light and air." This, from observation, I can quite believe. In planning such buildings, the owner and architect should ascertain the amount of accommodation that will give a fair, perhaps good, return on the money invested. To try and squeeze every pound out of the venture is a despicable variety of "sweating," and any so doing only meet their just deserts when they put on the last straw and break the camel's back.

"Granny's" in the grumps again. A back seat is always hard, I suppose, and particularly

so to old bones. The old lady was heard all over the shop last week, crooning to herself:—

"All behind, my dears, and we
Scarce excuse can stammer. Ah!
They got in front of us, you see—
Them willins—with a camera!"

GOTH.

AMERICAN ARCHITECTS ON COMPETITIONS.

AT the annual convention of the American Institute of Architects, held at Chicago on October 20, the following series of pronouncements and suggestions to promoters and architects on the management of competitions, drawn up by Mr. Charles E. Ilsley, the chairman of the Competitions Committee, was unanimously adopted, and ordered to be printed for gratuitous distribution to members:—

While the American Institute of Architects emphatically disapproves of architectural competitions as usually conducted, long experience having shown that they result almost invariably in disappointment and harm to all interests concerned, to the public as well as to the profession, and to owners equally with architects; and while the Institute advises that wherever practicable an architect should be selected individually in the same manner as with lawyers, physicians, and other professional men; still, where on Government work for any reason an architectural competition is unavoidable, the following precautions are suggested to both owners and architects as calculated to obviate the principal causes of miscarriage, and to enlist the co-operation of architects who will otherwise be likely to refuse participation in the competition.

1. An experienced architect of repute should be engaged by the owners at the start as consulting architect throughout the competition. All the papers and correspondence should be controlled by him. Of course, he will not participate as a competitor.

2. The rules and restrictions should be as few as possible, and so explicitly stated as to prevent misunderstanding.

3. Two kinds of competitions are customary—viz., an open and a limited competition. In the latter a certain number of architects are invited to submit designs, and all others are excluded. In the former the competition is open to every one. An open competition is often preliminary to a limited competition confined to those architects (usually three to six in number) whose designs received in the open competition have been placed highest.

4. Every invited architect should be paid for his competitive design the schedule commission of one per cent. on the estimated cost of the building. The architect whose design is placed highest should be guaranteed the work at the schedule fee of five per cent. for plans and superintendence. Unsuccessful designs should be returned free to their author immediately after the award is made; no portion of them to be used without the consent of their authors.

5. The site of the building should be given and the requirements as to accommodation, cost, &c. It might be well to arrange the requirements in two classes—viz., those which are arbitrary and must rigidly be adhered to, and those which are advisory only. As a rule, owners will find their interests promoted by making the list of arbitrary conditions as small as possible.

6. All transactions relating to the competition should be in writing, and recorded, and open to the inspection of each competitor.

7. A date should be fixed within which the awards should be announced and all premiums paid.

8. After the award all drawings should be open to the inspection of all competitors for at least 24 hours. In many cases an exhibition open to the public would be desirable.

9. The selection and premiation of the designs should be made by a jury, of which at least two-thirds should be disinterested and experienced architects, whose report should be in writing and accessible to each competing architect.

An hotel is about to be built at Stone Point, Fawley, Hants, from plans by Mr. Stanfield C. Greenwood, of Southampton, at an estimated cost of £4,000.

The highest chimney in Germany, and probably on the Continent, has just been built at Stolberg, near Aix-la-Chapelle. It is 407ft. high, and it stands, moreover, on an eminence which rises some 270ft. above the surrounding plain. The inside diameter of the stalk is, at the bottom, 16ft. 8in.; at the top nearly 10ft. The chimney, provision for ascent of which has been made by fixing iron steps in the masonry, has occupied six months in erection, and the work was carried out without accident.

At the last meeting of the local board for Erith, a letter was received from Mr. W. W. Cooper, of Hinxley, the newly appointed surveyor, stating his regret at having to decline the appointment at that late hour, his local board having pressed him to stay. It was decided not to proceed against Mr. Cooper, but the Board considered they had been very shabbily treated. The chairman said it was necessary to fill up the vacancy, and he submitted the name of Mr. Harold Hind, son of a member of the board, who would be just the man to take up the duties. Mr. Hind did not come forward in competition before because he had no prior experience! He proposed that Mr. Hind should be appointed on trial for six months, and then the berth could be thrown open to public competition. This was agreed to.

PRICES.*—LI.

(All Trade Discounts have been taken off, and Profit added.)

IRONMONGER, & Co. (continued).

SAFES, LISTS, & Co. (Chubb's, delivered only).

BURGLAR and fireproof doors and frames—		£	s.	d.

Engineering Notes.

LIVERPOOL.—A special meeting of the Mersey Docks and Harbour Board was held on Monday to consider the question of providing additional accommodation in the river for Atlantic passengers, and railway facilities connected therewith. Mr. G. F. Lyster, the engineer, reported that he proposed to lengthen the Prince's landing stage by 300ft. at its northern end, and to construct a timber jetty about 400ft. long for the coasting trade. It was also proposed to run along the centre of the jetty a line of rails connected with the main line and two hydraulic cranes, and to provide an extension of dock and shed accommodation. A covered passenger station was proposed, about 500ft. by 80ft., on the east side of the roadway. Three lines of rail were provided for, and at the north end there would be a block of buildings for refreshment and waiting-rooms, offices, &c. The engineer estimated the cost of these works at £180,000, independent of the railway passenger station at the south end, which would cost about £40,000, making in all £220,000. A committee recommended that steps should be taken next session to obtain Parliamentary authority for the execution of these works, also to provide a new landing-stage, 1,200ft. in length, with railway accommodation connected therewith, for the landing of cattle, &c., at an estimated cost of £350,000. A motion for the adoption of the scheme was carried.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

BIRMINGHAM ARCHITECTURAL ASSOCIATION.—On Saturday afternoon, the members of this association visited the terracotta works of Messrs. Joseph King and Co., at Netherend, near Stourbridge, and passed a considerable time in inspecting the different processes through which the clay passes. The visitors afterwards inspected the fireclay works of Messrs. King Brothers.—The annual conversation of the above association was held on Tuesday night at the Grand Hotel. The proceedings opened with a reception by the president (Mr. William Hale, F.R.I.B.A.), and among the members and guests present were Messrs. F. B. Peacock, W. H. Bidlake, C. E. Bateman, W. Hawley Lloyd, J. A. Cossins, H. Beck, Herbert R. Lloyd, J. H. Rogers, G. A. Cox, M. Cox, and A. Harrison. During the first hour those present were afforded an opportunity of examining the collection of drawings which had been got together for the occasion, prominent among them being the drawings of the Birmingham Assize Courts, by Aston Webb, some fine examples of pen-and-ink drawing by C. E. Mallows, Ernest George and Peto, E. J. May, H. H. McConnal, E. C. Bewlay, and water-colour drawings and sketches by W. H. Bidlake, G. A. Cox, and R. Phené-Spiers; whilst Mr. Hale sent a design for a new church at Stinchley-street, and Mr. C. E. Bateman some pencil sketches of domestic work; and some interiors were lent by Mr. Edward R. Taylor and Mr. J. Pratt. The reception was followed by a concert, at which recitations were given by Mr. H. Harvey and Mr. Whitworth Wallis, songs by Mr. Walter Crosbee, Mr. H. Monckton, and Mr. F. S. Hughes, and banjo songs by Mr. S. Lowcock.

BIRMINGHAM MASTER BUILDERS' ASSOCIATION.—The annual meeting of this association was held on Tuesday at the Grand Hotel, Colmore-row, Birmingham, Mr. C. H. Barnsley (president) in the chair. In the annual report the committee regretted that they were unable to state that the improvement in the state of the trade referred to in the three last annual reports had been maintained. All the manufacturing trades of Birmingham and the district had during the last twelve months experienced a great falling off of business, the result to a great extent of the keenness of foreign and other competition and hostile tariffs. The past year had been an eventful one in the history of the association owing to the strike of bricklayers and their labourers, which resulted in the arbitration clause in the rules being abolished, and an advance of 3d. per hour conceded; in other respects the rules remained as before. The continued decline of trade since this settlement had convinced the committee that they were fully justified in resisting to the utmost the demands of the

operatives. Notices for alteration of rules and increase of wages had been received from the carpenters and plasterers, and for alterations of rules only from the stonemasons. These would be considered in due course. The committee had felt it necessary, having regard to the present position and the future prospects of the trade, to give notices to the bricklayers and labourers to return to the rate of wages paid prior to April 1 last, also for other alterations. The committee had under consideration the revision of the schedule of daywork prices. The number of members had increased from 39 to 63; many of the new members joined the association while the strike was pending. The report and balance-sheet were adopted. Mr. W. Sapcote was elected president for the ensuing year; Mr. T. Rowbotham was elected vice-president, Mr. R. Bulley treasurer, and Mr. E. J. Bigwood secretary. The annual dinner afterwards took place, under the presidency of Mr. W. Sapcote.

SANITARY INSPECTORS' ASSOCIATION.—The opening address of the session of this association was delivered on Saturday at Carpenters' Hall, London Wall, by the chairman of council, Mr. Hugh Alexander, who congratulated the members upon the progress that had attended their efforts to unite sanitary inspectors under one association. Much still remained to be done to secure remedial legislation to enforce the proper remuneration of officers, and to improve the education, as well as to secure the efficiency, of candidates for the position of sanitary inspectors. He called attention to the evils frequently existing in back-to-back houses, and said that in London sufficient attention was not given to the necessity of houses being constructed on hygienic principles in all respects. Notable examples of this might be found in any district, not only in the East, but also in the West-end, and in close proximity to the most aristocratic quarters. They had continually complained of the defective state of the law which permitted such buildings to be erected. The reason which accounted for badly-built houses nearly always was, he asserted, to be found in the laxity of the architects concerned. He hoped the Royal Institute of British Architects would institute an inquiry and take steps to remove from its ranks those who, either wilfully or ignorantly, planned buildings in violation of the very first principles of sanitation. He suggested that the London County Council should be empowered, in conjunction with local authorities, to prohibit the erection of any dwellings, the plans of which evinced on the part of the architect ignorance of hygienic principles or disregard of the comfort and well-being of the people who might live in the houses.

CHIPS.

The foundation-stone of new schools, which are to be attached to the Roman Catholic Chapel at Sheffield, Staffs, were laid on Monday. The schools are to be built of red bricks, at a cost of £530, the architect being Mr. S. Loxton, and the builder Mr. Bantock, of Walsall.

At a meeting of the Bath City Council, on Tuesday, it was unanimously resolved to proceed at once with the new municipal buildings, from the amended plans submitted by Mr. J. M. Brydon. The contract with Messrs. Hayward and Wooster, builders, of Bath, for the erection of the buildings, was thereupon sealed.

The resignation is announced of Mr. Charles Fowler, district surveyor of Shoreditch and the Liberty of Norton Folgate. It is probable that the district will be amalgamated with some of the adjoining districts, and pending the decision of the London County Council, it has been placed in charge of Mr. Henry Lovegrove, district surveyor of South Islington.

A memorial slab to commemorate the late Mr. Oliver Heywood's deep interest in Chetham's College and Library, Manchester, has just been placed in the west wall of the entrance to the College library. The slab, which has been executed by Messrs. Earp and Hobbs, from the designs of Mr. J. Medland Taylor, of Manchester, architect, is of oblong form, and composed of Upton Wood stone. It bears the following inscription, carved in Gothic lettering:—"Pass not by without bestowing a thought of kindly remembrance upon Oliver Heywood, who, of his good will, did restore the dining-hall, reading-room, library, kitchen, dormitories, and cloisters between the years 1883 and 1890." During the seven years the restorations referred to were being carried out, Mr. Heywood insisted on his name not being mentioned in connection with the work.

Building Intelligence.

AVONMOUTH.—The foundation-stone of St. Andrew's Church was recently laid. The church will consist of chancel, nave, south aisle, and tower, and will seat 600 persons. At present the two west bays, the tower, and the vestry are omitted. The church is so designed that the north wall can be removed and another aisle added. The style is Decorated, and there will be elaborate tracery to the windows. The structure is of red stone, quarried at Shirehampton, and lined with Bath stone. Provision has been made for the tower on a large bed of concrete. The roofs will be covered with Broseley tiles, and inside they will be of pitch-pine, as the wood comes from the plane, neither painted nor stained. Ultimately the chancel will be laid with marble mosaic work, but this forms no part of the present undertaking. About £4,000 is being spent now, the contract for the entire scheme being rather over £6,000. Mr. W. Wood Bethell, of Westminster, is the architect; Messrs. R. Wilkes and Son, of Bristol, are the contractors; and Mr. G. Downs is the clerk of works.

BIRMINGHAM.—The Waverley-road Seventh Standard School was publicly opened last week. This is the first complete school erected by the Birmingham School Board for teaching a seventh standard. The school provides accommodation for 300 boys and 300 girls. It is a one-story building, and is arranged with a central assembly hall, surrounded by classrooms, workrooms, and laboratories. The assembly hall is 68ft. by 30ft. There are four entrances to the building, two for each sex, connected by a long corridor, which give access to the assembly hall and the various classrooms, laboratories, and workrooms, as well as to the school of cookery. Adjoining each entrance is a lavatory and cloakroom, over which are rooms for masters and mistresses. In the girls' division there are five classrooms, giving accommodation for 48 in each, and a cookery school, with accommodation for 60. In the boys' department there are six similar classrooms, each for 48 boys, a chemical laboratory, 60ft. by 30ft., a workshop of the same size, with a store for timber, and a lecture-theatre, seating about 100 children, with a preparation-room adjoining. Between the preparation-room and the laboratory are arranged a balance-room, combustion store, chemical store, and apparatus store. On the first floor over this a room is provided for preparing diagrams for lecturing purposes. The chemical laboratory is fitted up with six work-benches placed down the centre of the room. The architects are Messrs. Martin and Chamberlain, and the builder Mr. T. Rowbotham. The head master is Mr. H. K. Frew, late of the Central Higher Grade School at Leeds.

BRISTOL.—The designs prepared for the new Bristol Empire Palace of Varieties by Messrs. Wylson and Long, of 15, King William-street, Strand, have been passed by the local authorities, and a contract for its erection has been arranged with Mr. Frank Kirk. The new theatre is intended to be opened next Whitsuntide with a strong variety company. The building will be situated in the busiest portion of the city, and has been designed to be used not only as a theatre, but, by a simple mechanical arrangement, the stage can be removed to give place to a circus ring.

CORNHILL.—A banking-house has just been completed at 50, Cornhill, for Messrs. Prescott, Dimsdale, Tugwell, Cave and Co., Limited. The building has been designed by Mr. Henry Cowell Boyes, architect, of Lincoln's Inn-fields, in a Georgian Classic style, in which red brick, relieved by Portland stone dressings to the windows and cornice, is employed, with grey granite basement and polished columns supporting a triple-arched window to the main banking hall. Stone balconettes are introduced to the second-floor windows. On the ground floor is a large hall, about 68ft. long by 37ft. wide, and 21ft. high, the walls lined by slabs of Derbyshire alabaster, which are divided into panels by mahogany Ionic pilasters and entablature along the lower portion of the walls, and a mahogany panelled dado. At the inner end is a directors' on-duty room and secretary's office, divided by a glazed screen. A staircase of teak, with mahogany balustrading and dado, leads to a gallery on one side of the bank and a mezzanine story for clerks. On the first floor are the board-room,

secretary's and staff rooms, luncheon and waiting room, all having mahogany doors and fittings, and a lift from kitchen to luncheon room. The two upper floors are set apart for the residential clerks. The hydraulic lift has been provided by Messrs. Waygood. One interesting feature of the new bank is the existence of fragments of the ancient Roman wall in the sub-basement. The buildings have been carried out by Messrs. W. Cubitt and Co. Mr. Payne was clerk of the works. We may add the cost has been about £25,000, and the bank has been provided with Shorland's Manchester stoves.

LONDON COUNTY COUNCIL.—At Tuesday's meeting of this body, the Parks Committee reported that the question of the purchase and maintenance of the Albert Palace was still under their consideration, and they hoped in a fortnight to make a report to the Council on the subject. As, however, it would be necessary, in the event of the Council deciding to undertake the maintenance of the Palace, to obtain power from Parliament for the purpose, and the necessary *Gazette* notice must be prepared this week, they recommended: That the Parliamentary agent be instructed to include the matter in the *Gazette* notice of one of the Council's Bills, and that the Parliamentary Committee be authorised to take any necessary preliminary measures with a view to the insertion in the Bill of a Clause empowering the Council, if it so resolved, to accept and to maintain for the public use the Albert Palace and grounds.—The report was adopted.

MAWDESLEY.—The reopening of Mawdesley parish church, near Ormskirk, which has been undergoing restoration, took place on Wednesday week. New benches have been provided throughout of pitch-pine, and arranged with central and two side passages. A gallery has been provided at the west end, while new screens have also been erected. The old flat ceiling has been removed, and the roof left open, being finished in plaster of cream colour, and having the timbers left visible. The work has been carried out by Messrs. Moore Brothers, contractors, of Rawten-stall, from the designs and under the superintendence of Mr. R. Knill Freeman, F.R.I.B.A., of Bolton and Manchester.

NEWCASTLE-ON-TYNE.—The Hotel Metropole was opened on Monday. It consists of two older hotels, in Clayton-street, converted into one, and much altered and renovated internally. There are two entrances from Clayton-street, connected by a corridor passing in front of the offices and business department. The main staircase is opposite the south door. On the ground floor are, with other apartments, a private dining-room, 40ft. by 24ft., smoking-room and billiard-room, 40ft. by 22ft. Opening from the billiard-room buffet, a smoking-room, and lavatory accommodation. The remaining public rooms are on the first floor. They consist of a commercial-room, 40ft. by 24ft., a ladies' dining-room, a private dining-room, and suites of apartments, comprising bedrooms and sitting-rooms. On the upper floors there are sixty bedrooms. In addition there are stock-rooms. Messrs. Lamb, Armstrong, and Knowles, who were the architects for the Grand Hotel and the Grand Assembly Rooms, were the architects. Mr. Tyrie, of Gateshead, had the contract, and Messrs. Green and Son, Grey-street, Newcastle, have done the decorative work.

RICHARD'S CASTLE.—The Foster Memorial Church was formally consecrated by the Bishop of Hereford last week. It has been built from plans by Mr. R. Norman Shaw, R.A., at the sole cost of the widow and daughters of the late Major Foster, replacing on a more convenient site the old parish church now disused. The outside stone is local, and the inside stone is dressed Grinshill. The nave and south aisle are seated to hold 300 persons, and one of the windows is an exact facsimile of one in the old church, having the ball-flower carved outside. The tower is semi-detached, and contains a tenor bell of the weight of 40cwt., cast by Messrs. Taylor, of Loughborough. A cradle for a full peal of eight bells is fixed in the tower, should they ever be added. The low chancel wall is surmounted by an iron screen, with gates; the hanging lamps are also of wrought iron. In the chancel are three old brass Italian hanging lamps. The pulpit and the organ-case are carved in walnut; the choir-stalls are of oak, carved with a vine pattern in perforated work. Above the altar a triptych is

placed. It contains seven panels. The centre panel represents the Crucifixion with two attendant angels. The Blessed Virgin is depicted in the panel on the immediate left hand of the centre, and St. John is shown on the right hand. Angels and saints are depicted on the shutters. The paintings in the triptych, together with the decorations of the east wall, have been executed by Mr. C. E. Buckeridge, of 21, Mortimer-street, London, W. Messrs. Farmer and Brindley made the framework of the triptych. The organ is being built by Messrs. Abbott and Smith, of Leeds, the case being of carved walnut, with spotted metal pipes. The general contractors were Messrs. Thompson and Son, of Peterborough.

SOUTHAMPTON.—The foundation-stone of a new post-office for this town was laid on Tuesday week. It will occupy the site of the old post-office and adjoining premises, and will extend from High-street to Back-of-the-Walls. The style of architecture is to be French Renaissance, and plans have been prepared by Mr. Henry Tanner, F.R.I.B.A., of Her Majesty's Office of Works. The front building is to be four stories in height. The public office will be 34ft. 4in. by 25ft. 6in., and 15ft. in height. At the back is the instrument room. On the first floor, offices for the postmaster and his clerks will be provided. On the second floor there are offices for other clerks, and the third floor will be devoted to the caretaker. The front elevation up to the first floor level will be faced with tawny terracotta, while the upper stories will be faced with red Fareham bricks and terracotta dressings. The sorting office will be 192ft. 2in. long, with an average width of 43ft. The contract has been secured by Messrs. Crook and Sons, of Northam, and the building will be supervised by Mr. James Atkinson, of Her Majesty's Office of Works, as clerk of works.

STANTON-ON-HINE HEATH.—The parish church was reopened last week after restoration. The mean iron-framed eighteenth-century windows have been replaced with tracery in the Decorated style. The plaster ceilings have been removed, and the original roof-timbers exposed to view. The roofs of nave and chancel have been covered with oak boarding and Broseley tiles. The gallery and box pews—the latter extending into the chancel—have been removed, and the nave has been re-seated with open sittings in pitch-pine. When the south wall of nave was cleared of ivy and plaster an octagonal pillar, intact, with cap and base, and portions of two arches with the corresponding jambs, were discovered near the east end, showing that there had once been an aisle or side chapel. These arches have been carefully restored. New oak doors, with wrought scroll hinges, have been fitted to porch and vestry, as also to the Norman doorway on the south side, which had previously been bricked up. The whole of the nave floor has been tiled. The old carved oak Jacobian pulpit has been refixed on a stone base. The tower, the upper portion of which is of fifteenth-century date, has had new tile roof, the decayed stone pinnacles replaced with new ones; vane fitted with new copper weathercock and lightning conductor. The chancel arch has been rebuilt, and other new works are parapet wall and gable cross, chancel steps and dwarf wall, three-light east window, angle buttresses at east end, coping and gable cross, Runcorn stone reredos, with alabaster shafts and white marble cross, encaustic tile floor, oak choir stalls, vicar's seat, and prayer-desk. The old oak panellings from pews have been fixed as a dado to chancel, and the old oak balustrade has been refixed as a Communion rail. The whole of the work has been carried out from the designs and directions of Mr. A. B. Deakin, architect, of Castle Chambers, Shrewsbury, the general contractor being Mr. Thomas Chaloner, builder, of Hanwood. The total cost of the restoration has been about £1,300.

H.M. Board of Works is carrying out a scheme for the preservation of the ceilings and walls of certain portions of the historical apartments of Holyrood Palace. No attempt has been made to restore the colouring, but simply to preserve what remains, and this it is believed has been accomplished by the careful application of several coats of transparent varnish. The old stained look of the ceilings has not been altered by this operation. The work is being done by Mr. A. Muirhead, 14, Castle-street, under the personal supervision of Mr. W. W. Robertson, of the Board of Works.

COMPETITIONS.

ABERDALE INTERMEDIATE AND TECHNICAL SCHOOL COMPETITION.—In the above competition the assessor was Mr. Ewan Christian, F.R.I.B.A., and the selected design was that submitted by Mr. J. H. Phillips, M.S.A., architect, St. John's Chambers, Cardiff. The selection has been approved by the committee, and Mr. Phillips has been appointed to carry out the work. The estimated cost is £3,300.

ALLOA, N.B.—At a joint meeting of the Burgh Commissioners and County Council representative held at Alloa on Monday, a short list of two sets of plans for a fever hospital were submitted from Messrs. J. Melvin and Son, architects, Alloa, and Messrs. Johnstone and Burnie, architects, Edinburgh. After consideration of a special report on the plans by Mr. Whitson, measurer, Glasgow, the meeting unanimously resolved to accept the designs submitted by Messrs. Melvin, the estimated cost of which is about £5,000. The plans provide for an administrative block, having ample accommodation for doctors' rooms, matron's rooms, kitchen, &c., with bedrooms for servants, &c., on the top flat. The design of the building is a simple treatment of the Old English style, the gables being filled in with timber and plaster, and the architects have endeavoured to give the effect of a cottage hospital. The total accommodation provides for 24 beds in the main pavilion, and four in the probationary wards. It is proposed to erect the hospital on a site near Parkhead farm, to the north of the town of Alloa, and the work will be proceeded with shortly.

NEWCASTLE-ON-TYNE.—The assessor appointed by the directors of the Newcastle-upon-Tyne Masonic Hall Company, Limited (Mr. C. Barry, P.P.R.I.B.A., Grand Superintendent of Works for England), has awarded the first premium to the design submitted by Mr. John Johnson, A.R.I.B.A., 9, Queen Victoria-street, London, and the second premium to the design submitted by Mr. H. T. Bonner, A.R.I.B.A., King-street, Cheapside, London, E.C.

"OWEN JONES" PRIZES.—This competition was instituted in 1878 by the Council of the Society of Arts, as trustees of the sum of £400, presented to them by the Owen Jones Memorial Committee, upon condition of their expending the interest thereof in prizes to "Students of the School of Art who, in actual competition, produce the best design for household furniture, carpets, wall-papers and hangings, damask, chintzes, &c., regulated by the principles laid down by Owen Jones." The prizes are awarded on the results of the annual competition of the Science and Art Department. Six prizes were offered for competition in the present year, each prize consisting of a bound copy of Owen Jones's "Principle of Design," and a bronze medal. The following were the successful candidates:—Robert Dow, School of Art, Glasgow: design for a printed hanging. Florence Morris, School of Art, Hertford: design for a plate. William Spiers, School of Art, Glasgow: design for a hanging. Ella B. Ginn, School of Art, Hertford: design for wall-tiles. Ada Hasleham, School of Art, Cavendish-street, Manchester: design for a printed cotton. Joseph G. Slade, School of Art, Cavendish-street, Manchester: design for calico prints.

WAKEFIELD.—The County Council of the West Riding of Yorkshire invite competitive plans for the erection of council chamber, committee rooms, and offices at Wakefield. Premiums of £200, £100, and £50 respectively are offered for the three best designs.

WALSALL.—At the annual meeting of the corporation, held on Wednesday week, it was decided to appoint Mr. J. MacVicar Anderson, P.R.I.B.A., as assessor to report on the competitive plans received for the new Town Hall, at an inclusive fee of 110 guineas.

The plans and scheme of Mr. A. P. J. Cotterell, C.E., of Bristol, have been adopted for an improved supply of water to Bruton, Somerset.

Mr. Mundella opened on Thursday the new buildings of the Maria Gray Training College, which have been erected in Salisbury-road, Brondesbury. The new college and the adjoining Brondesbury and Kilburn High School have been erected, from the designs of Mr. J. Osborne Smith, at a total cost of £11,500. Accommodation is provided for 75 day students and 200 children.

Correspondence.

"SEASIDE ARCHITECTS."

To the Editor of the BUILDING NEWS.

SIR,—Your very interesting article of a few weeks ago, on "Seaside Architecture," leads me to make a few remarks, not so much on the architecture as on the architects of our seaside resorts, or, at least, as regards my experience of them. I am a young architect, fresh from a first-class office in the North of England, and have settled down here with the intention of commencing a practice. The state of the profession has struck me rather peculiarly. In this district architects advertise in the local papers just as any tradesman would; the way work is canvassed is something original to me. As soon as it is made known that a party intends building he is at once besieged, each architect (so called) trying to out the other out with temptingly low offers. One and a half and 2 per cent. seem to be the rule—5 per cent. a thing almost unknown. An idea as to the status of the profession locally may be gathered from the fact that recently a certain gentleman sent round to all the architects in the place, asking for tenders for the preparation of certain plans!

Two or three local builders have informed me that they are constantly receiving circulars begging for work from one of these "architects, surveyors, land and estate agents, &c.," accompanied by a lithographed sheet of elevations of work done by him.

Everyone dabbles in plan-drawing here—joiners and bakers, beer-sellers and fishmongers—all join in doing the poor architect out of his dues.

As regards the architecture of the district, the less said the better—it may be easily inferred. Whether architecture is an art or a profession, it appears to me that something ought to be done. May the much-hoped-for Registration Bill come soon, is the fervent wish of—Yours, &c.,

HERBERT WADE.

St. Annes-on-the-Sea, Lancs.

MR. HENRY PARSONS.

SIR,—In September last a report of the conviction at Lambeth Police-court of Mr. Henry Parsons, the well-known district surveyor for Lambeth and Camberwell, for travelling on the London and South-Western Railway without previously paying his fare, was widely circulated by the Press. Mr. Parsons was so unnerved at the charge, coupled as it was with a statement altogether unexpected by him, and quite unsupported by positive evidence, that he had for many years been in the habit of travelling on the line without payment of his fare, that he was unable when before the magistrate either to properly cross-examine the witnesses or to put before the Court any complete explanation of the circumstances under which he had travelled down on the evening of June 28th and upon the morning of June 29th without a ticket. There was no appeal from the conviction, and though Mr. Parsons circulated an explanation amongst his friends, he was unable, on account of its length, to give it wide publicity.

Within the last few days an opportunity has been afforded Mr. Parsons of stating the facts of the case fully on oath, and of producing evidence in support of his own statement, a motion having been brought forward in the Chancery Division of the High Court to remove him from the position of Receiver in a pending action on the ground of the above mentioned conviction.

The result of the proceedings last Friday before Mr. Justice Chitty, was the continuance of Mr. Parsons in the position of Receiver, at the desire of various eminent counsel representing the parties to the action, who expressed their complete satisfaction with the explanation given by Mr. Parsons and their respective clients' entire confidence in him.

The position in which Mr. Parsons was thus continued by the Court involves the receipt by him of about £7,000 per annum, and is therefore one of great responsibility.

We are sure that you will feel it right to give publicity to this result, and thanking you in advance,—We are, &c.

SHAEN, ROSCOE, MASSEY, AND CO.
8, Bedford-row, W.C., Nov. 15.

Intercommunication.

QUESTIONS.

[10886].—**Breaking Weight.**—What is the breaking weight in tons of a post 8in. by 8in. by 12ft. long, adopting the formula $BW = 7.81 \frac{D^4}{L^3}$ and how can I find the

side of a square wood post when the weight to be supported and length of post are given? In calculating the stresses of a rolled iron beam uniformly loaded and fixed at both ends should, the formula be $\frac{WL}{12D^3}$ and in finding

such stress should, any allowance be made for the web, and if so, how much?—STUDENT.

[10887].—**Cubing Buildings for Approximate Cost.**—Would one or two of the numerous readers kindly inform me the correct way to take out these dimensions, and am I right in taking outside of walls both ways and from the bottom of footings or concrete to half-way up the roof, irrespective of pitch of roof? An early answer will oblige.—IN DISPUTE.

[10888].—**House Drainage.**—The drainage of a large house, which has been recently reconstructed with new drains, disconnecting chambers, and ventilation, ultimately empties into a cesspool, which receives all wastes from baths, sinks, w.c.'s, &c. This cesspool is covered with an air-tight man-hole cover, and the overflow, running into a ditch, is trapped also, thus making the cesspool air-tight. I am told that this air-tight cesspool, which is emptied once in six months, and is no apparent nuisance at present, must be ventilated, or the sewage gas generated will force, or, at any rate, come through, the water in the trap, and that a ventilating pipe would relieve the pressure. I have read several textbooks, but the writers do not agree as to the advisability of such ventilation or not. Can any of your readers put me right from actual experience?—FIFTEEN YEARS' SUBSCRIBER.

[10889].—**Red Spider.**—About eighteen months ago I completed a house of considerable size in the outskirts of this town. The house is built of brick of a deep red colour, and the stonework is also red in tint from the Corncockle quarries of Dumfriesshire. The carpenter's work is of red deal, and the joiner's work of oak and red deal. During the last summer the house has been visited by a plague of insects, infinitesimal in size and red in colour. These covered the whole of the windows, both inside and out, particularly those of the ground floor. What these insects are, or where they come from, we have been utterly unable to discover. Have any of your readers had a similar experience, and if so will they kindly enlighten me as to what these insects are if not a spider, where they come from, and if any means can be adopted to prevent the recurring of such unwelcome visitors?—J. M. BOTTOMLEY, Architect, Middlesbrough.

[10890].—**Surveyors' Charges.**—Where a building is erected under a schedule of prices, is it usual for the builder and building owner each to pay their own surveyors' charges for measuring up work?—TAPR.

[10891].—**Covered Way.**—Is it necessary to obtain the London County Council's permission to erect an iron and glass covered way at first floor level across a private yard to connect two buildings.—FIREPROOF.

REPLIES.

[10878].—**New Lights in Old Boundary Walls.**—An adjoining owner has a legal right to insert new windows in boundary wall, but the owner of yard and gateway has a right to block out the light coming to the window by erecting a high fence or building as proposed over the 8ft. space. If possible, come to terms with adjoining owners.—G. H. G.

[10880].—**Fireproof Floors.**—I should be inclined to recommend either Dennett's or Homan and Rodger's system. Homan's patent floor appears to fulfil the requirements of domestic buildings of a large size, though other methods may be preferred in special cases. It would be difficult to say without plans of the buildings which system would be the best. For small dwellings a simple system of iron joists, with some intervening stiffener for a layer of concrete, is called for. No doubt local authorities of large towns will find it necessary to restrict the use of wooden floors for large buildings, whether domestic or otherwise, and to make it compulsory to adopt fireproof construction.—G. H. G.

[10882].—**Water Pipes.**—I should recommend the lead-lined block-tin pipes if the water is very soft. Cast iron is well adapted for large pipes, but for small ones the danger of rusting is against their employment. Wrought iron and steel pipes are now used with much success, and they are cheap and durable, and can be easily jointed and bent, the only objection being their liability to rust. I am not sure if wrought-iron pipes are now in the market protected against this. Probably some correspondent will be able to give information. In America and the colonies wrought-iron and steel pipes are largely used.—G. H. G.

A meeting-house and schools for the Society of Friends were opened last week in Rochdale. The building, two stories high, is built of Horwich stock bricks, with stone dressings and overhanging eaves. The schoolroom occupies the ground floor, and seats 150 persons. The meeting-room on the first floor will seat about 150 persons, is finished in pitch-pine, varnished, and has a half-open roof. The ventilating is effected by means of Messrs. Robert Boyle and Son's air-pump ventilators. The work has been carried out from plans prepared by Mr. J. H. Burton, architect, of Radcliffe, who superintended the erection of the building. The chief contractors were:—Brickwork, Messrs. Makin and Sandford; stonework, Mr. George Openshaw; woodwork, Messrs. Collier and Smith—all of Radcliffe. The cost was £900.

Legal.

LEASES AND "OUTGOINGS."

THE Public Health (London) Act 1891 is likely to give a good deal of trouble to leaseholders. Of course this statute is only an extension of the Public Health Act 1875 to the metropolis. But in regard to the sanitary requirements it affects a different class of property, and will be found to bear hardly on many lessees of old town houses. The idea in the minds of most of its promoters was, doubtless, to throw the burden of repairing sanitary defects in town dwellings upon their owners, and with this view the Act provides that in the case of a nuisance arising from structural defects the landlord is the proper person to be served with notice to abate, and the duty is cast upon him of remedying the defect. But those who thought that this clause in the Act would throw the burden on the ground owner forgot the covenants in the leases under which most of our town dwellings are held. It is true the law makes the landlord responsible to the public; but, generally speaking, his lease contains stringent clauses as to repairs and the payment of all "outgoings," under which the lessee is made liable, over to him. The Act, therefore, does its best by rendering the owner in the first place compellable to abate the nuisance—which is well; though the private contract between the parties to the lease may ultimately cast the burden upon the tenant, for whom it was really never intended.

This state of things has just been exemplified in the recent case of *in re Bettingham* (*Times*, Nov. 6), where the question arose over a house in Delahay-street, Westminster. The lease contained clauses under which the tenant was to pay all rates and taxes, and also all "assessments and outgoings whatsoever, whether Parliamentary, local, or otherwise, now or at any time, during the said term, to be imposed, charged, or assessed upon the said premises, or the owner or occupier thereof." The tenant found the drainage defective, and applied to the landlord to do the needful repairs, stating that, unless he did, there would be an application to the sanitary authorities, under the Act, by whom he would be compelled to abate the nuisance. The result was an arrangement under which the tenant did the work, it being agreed that the cost should be ultimately borne by the party who would be legally liable had the landlord been, in fact, called upon to do it under the Act of 1891. A summons to decide this question was taken out, and it came on for hearing before Mr. Justice North, who now held that, by the words above quoted from the lessee's covenant, it was clear that they were liable. He based his decision specially on the word "outgoing," and the earlier case of *"Budd v. Marshall"* (L.R. 5, C.P.D. 481), where tenants had been held responsible on the word "duty" in a similar covenant. He also held that even if the defect arose from ordinary wear and tear and long user, for which the lessees were not liable under their covenant to repair, still, they would be responsible upon their other covenant as to "outgoings" for which the landlord had had to pay the local authorities.

FRED. WETHERFIELD, Solicitor.

1, Gresham Buildings, Guildhall, E.C.

NOTE.—All questions for reply in this column must be headed "BUILDING NEWS," and must reach my offices, as above, by Tuesday morning to insure answer same week.

LEGAL INTELLIGENCE.

THE BUILDER AND HIS PROPERTY.—At Hartlepool Petty Sessions on Tuesday week William Oddy, builder, of West Hartlepool, appeared in answer to a summons charging him with allowing a certain portion of his property situate in Frederick, Back Frederick, and Hermit-streets, Throston, to be in such a condition as to be dangerous to health. Evidence was given by Mr. J. Bridges (sanitary inspector), Mr. H. C. Crummach (borough engineer), and Dr. Rawlings (medical officer). The Bench eventually made an order for the nuisances to be abated within 21 days. There were other summonses against defendant for similar defects, but these were adjourned, he promising to abate the nuisance.

BREACH OF BUILDING LAWS.—Mr. J. Lavery, Great Patrick-street, Belfast, was charged at the police-court of that city on the last inst. with

building, and proceeding with buildings, in Marshall-lane, despite the refusal of the council to pass the plans. Mr. Munce, the assistant surveyor, and Mr. Meyer stated that the plans were never approved of, and that Mr. Lavery had received notices by the half dozen to that effect, and other witnesses proved that he had proceeded with the building despite this. Defendant was fined £10.

IN RE J. J. LUKE.—The examination of John James Luke, builder, of Park View, Alverstoke, took place at Portsmouth Bankruptcy Court last week. The statement of affairs showed gross liabilities amounting to £2,556 19s. 10d., of which £512 13s. 4d. was expected to rank for dividend. The assets were valued at £245 13s. 6d.; leaving a deficiency of £266 19s. 10d. The debtor attributed his failure to the loss of over £110 by the Portsea Island Building Society; to slackness of the building trade, and to pressure by creditors. The debtor admitted that he failed three years ago, and that he obtained his discharge about a twelvemonth afterwards. He was allowed to pass.

WOOD AND IRON VERANDAHS.—The following was a case under the Metropolitan Building Act. At the South-Western Police-court, on the 11th inst., Messrs. Strudwick and Co., builders, Ealing, were summoned for erecting a wood and iron verandah contrary to section 26, and without first giving notice to the district surveyor. The case was before the court on the 30th September last, when Mr. Cheston, the district surveyor, agreed to an adjournment to enable the defendants to apply for the sanction of the London County Council. Mr. Cheston said he found that no application had been made to the Council, and also that he had received no communication of any kind respecting the structure. Evidence having been given as to the irregularity, the magistrate made an order for removal, and inflicted a fine of £5 and cost for neglect to give notice.

ACTION AGAINST AN ARCHITECT AND SURVEYOR.—At the Wantage County-court last week Judge Snagge heard a claim by Wm. Bass Sivell v. H. William Hanson for £50 salary and damage for wrongful dismissal. The plaintiff, who lives in London, advertised for a situation as architect's assistant and came in communication with the defendant, an architect, of Letcombe Regis, and surveyor to the Wantage Highway Board. Defendant offered plaintiff £2 a week for the first six weeks and £2 10s. for the next six months, but at the end of the first six weeks discharged him. It was claimed that a contract was entered into for six months, and salary for overtime was also claimed. Plaintiff had brought his wife to Wantage and settled there. His Honour gave judgment for £10 damage for dismissal and £6 10s. for overtime and costs.

AN ARCHITECT'S CLAIMS FOR FEES.—At Newport County-court on Thursday in last week, before his Honour Judge Owen, the case of Swash v. Remy and Gilmore was heard. The plaintiff was Mr. A. Swash, architect, Newport, and the defendants were Newport pilots. The claim was one for fees for plans and superintendence of the erection of houses for the defendants. There was also a counter claim on the part of the defendants, who alleged negligence on the part of Mr. Swash. Plaintiff stated that in February, 1891, he was engaged by the defendants to obtain a site and draw out plans for two houses to be erected in Waterloo-road. He prepared two sets of plans, owing to the first plans being too expensive. He was instructed to prepare the new plans for houses which were not to exceed £600 each. Defendants were satisfied with the new plans, and tenders were obtained. The lowest was that of Mr. Westacott, the amount being just over £1,200, which was accepted. Witness had given a final certificate. In cross-examination, witness said that his certificate, which said that in "the architect's opinion the work was satisfactorily completed," was not given in the usual form. Witness admitted that the work was not completed on the 17th August last, and no work had been done since. He then wrote to the defendants saying he was willing to refuse to give a final certificate if the defendants would indemnify him against legal proceedings. On September 6th he was waited upon by a deputation from the Master Builders' Association, and on the same date he gave his final certificate, after examining the plans, specifications, and estimates. The principal item in dispute was as to the mullions of the windows, which, it was contended the plans showed, should be 14in., whereas the contractor had put in 9in. mullions. In re-examination, witness produced Westacott's bills of quantities, which showed that the contractor had estimated his contract on 9in. mullions. Witness considered that defendants had received full value in the houses, and he was willing to give defendants £100 more for the houses than they had cost. Mrs. Laura Gilmore stated that she was present at the interview which her father-in-law had with Mr. Swash. Defendant was instructed to prepare plans for houses to cost between £500 and £600. Witness had negotiated for the sale of the site. Henry Rry, one of the

defendants, and father of the last witness, said that he instructed plaintiff in the first instance to prepare plans for a £600 house; he left the negotiations to his daughter, and she several times in his presence told the plaintiff that they wanted £600 houses. Defendant had never given Mr. Swash instructions to prepare a plan for stable, &c.; neither did he instruct plaintiff to negotiate for the purchase of the site. Mr. W. H. Dashwood Capel, architect, Cardiff, stated that the back walls showed evidence of damp, and should either have been slated or cemented. Mr. Edward Bruton, architect, Cardiff, agreed with the last witness, and said that the windows were not wind and water-tight. Mr. Charles Miles, builders' surveyor, agreed with the evidence of the last two expert witnesses. After hearing expert evidence on behalf of the plaintiff, his Honour decided that the plans showed that the walls should have been 14in., and said that the plaintiff had given his certificate improperly, and he expressed a strong opinion upon the fact that he had altered his views as to the original plan after receiving a deputation from the Master Builders' Association. He gave judgment for the plaintiff for £12 11s. 6d., and judgment for the defendant on the counter claim, evidence to be given as to the amount of damage at the next court.

MAXIMUM HEIGHT OF CORNER BUILDINGS.—Mr. Curtis Bennett heard a summons on Friday against Messrs. Lawrence and Son, builders, for erecting a block of residential flats at the corner of Kensington-court of a greater height than the width of the new street in which they were situated. The building is situated on the western side of Kensington-court, with a flank to Kensington-road, and is 74ft. in height, being, if measured from the court, 25ft. higher than allowed by the Act. For the defence, Mr. Dickens contended that the building was in the Kensington-road, and not in Kensington-court. It was one building with one entrance. According to the award in the Appellant Court of the London County Council the building was in Kensington-road. Mr. Curtis Bennett found as a fact that the building was in Kensington-road, and dismissed the summons. In dealing with the question of costs, the magistrate said that as the County Council had held their hands from April to October, he should order them to pay 10 guineas costs.

RIVAL BUILDERS.—At the Leyton Police-court, on Friday, Edgar Allen Chatterton, a builder, was summoned for threatening to have Edward James Hannen, a caretaker, murdered. The defendant entered into an agreement to put up certain houses in Albert-road, and obtained an advance from a building society upon the security of the houses. He left the houses unfinished, and the society took possession, and entered into a contract with a Mr. Chapman to complete them. The defendant went on to the premises, pulled down a bill, and threatened the complainant, who was the caretaker. The defendant was bound over in £10 to keep the peace. Chatterton was further charged with threatening William Faithful Chapman, the builder who is completing the houses, and he was also bound over to keep the peace in this case. He was also summoned for assaulting Mr. Chapman, and was fined 1s. and costs. A further summons against him for damage was withdrawn.

REVERSIONARY INTERESTS IN RIGHTS TO LIGHT.—LANE V. KELLY AND ANOTHER. —In the Queen's Bench Division on Monday, Mr. Justice Wright, sitting without a jury, heard an action by the owner in fee simple of houses and workshops, Nos. 3, 4, and 5, Bath-court, Clerkenwell, subject to leases granted for 21 years from July 10, 1885. The defendants in May last erected walls and houses 69ft. high opposite the plaintiff's premises at distances varying from 22ft. to 34ft., the result being to obstruct the windows in plaintiff's premises, and render them dark, unwholesome, and of less value, so that plaintiff's reversionary estate has been injured. The defendants denied that any injury had been caused to plaintiff's premises, and pleaded that all that was done by them was done with the full knowledge of plaintiff. Evidence was called on plaintiff's behalf to show that since the defendants' buildings had been erected the light had been diminished. For the defence, evidence was called to show that the original buildings opposite plaintiff's premises were only 10ft. away, and that in fact plaintiff's light and air were better now than formerly. Mr. Justice Wright, in giving judgment, said that as to No. 3—the warehouse and workshop—he had come to the conclusion that the top floor had not been obstructed by the defendants, and that the lower floor had not so good a light as formerly, the defendants' buildings being three times as high and twice as far off as before. Looking, however, at the cases of "Kino v. Rudkin" and "Kelk v. Pearson," it seemed to him that the question for him to decide was not whether there had been a diminution of light, but whether there was enough left for the reasonable use of the houses. He had come to the conclusion that, as to No. 3, enough light was left, and plaintiff must fail as regards that part of his case. As to Nos. 4 and 5—the dwelling-houses—

he thought plaintiff was entitled to recover damages, and adopted the view taken by plaintiff's expert, who put it at £2 10s. per annum. His judgment would therefore be for plaintiff for £30 damages and costs.

ARBITRATION AS TO REPAIRS AND FIXTURES.—In the Queen's Bench Division on the 8th inst., before Mr. Justice Grantham, the case of Robert Cook v. W. F. Tredwell and W. H. Dawes, of Upland House, Bath, executors of Solomon Tredwell, came on for hearing on further consideration. The action, which was for breach of two covenants to repair and the wrongful conversion of fixtures, originally came before his lordship and a jury in May last, and was, by consent, referred to Mr. Squarey, architect and surveyor, of Salisbury. The arbitrator sat at Bath, and found that all the repairs which defendants were called on to do were executed, but it was admitted that the work was not done within the two months specified by the covenant. For the conversion of fixtures Mr. Squarey had awarded the plaintiff £29 15s. Mr. Pollock now argued that as the repairs were not executed within the two months provided by the covenant, that was a technical breach, and entitled the plaintiff to the £2 which the defendants had paid into court. He also asked for judgment as to the question of the fixtures. Dr. Blake Odgers, for the defendants, argued that there could be no justification for paying out to the plaintiff the £2 lodged in court. He contended that the defendants had substantially won on the fixtures, because, while the plaintiff claimed £307, he had been awarded £29 15s. Mr. Justice Grantham said his *indemnity* *for* the defendants upon all the issues as to repairs, and with costs, except the arbitrator's costs; the £2 paid into court must be paid out to the defendants. There must be judgment for the plaintiffs on the issue as to the fixtures, and costs, except, again, the costs of the arbitration. The defendants would have the general costs of the suit, and each party must pay his own costs of the arbitration, and half of the arbitrator's fees.

IN RE W. F. ROBERTSON.—The debtor, who lately carried on business as a cement manufacturer at the West Drayton Cement Works, passed his examination on Tuesday upon a balance-sheet which showed unsecured liabilities £8,894, with assets £293.

CLAIM BY AN ARCHITECT.—At the Crewe County court on the 9th inst., George Balshaw, architect, Southport and Crewe, sued T. R. Hunt, draper, Crewe, for £18 12s. for plans and sketches prepared and other work done in connection with a house which the defendant had had built. The plaintiff stated that he called upon Mr. Hunt, taking with him some plans he had by him. The defendant made some suggestions as to alterations, and fresh sketches were prepared. He spent 49 hours in the preparation of the plans. Subsequently, at the defendant's request, he took a sketch of a house at Southport, and at a later date went to the site of the proposed erection and took the levels. Mr. Hunt seemed perfectly satisfied with the plans at that date; but subsequently he told him that he had determined to employ a Crewe architect, as he was afraid a Southport man could not give so much attention to the work. On examining his diary, the plaintiff found that he had spent 120½ hours altogether on the defendant's work. Mr. Chester said the plaintiff called upon Mr. Hunt and asked for the job—in fact, touted for it, and it was for this calling apparently that the 16 guineas was to be charged. The defendant bore out this statement, and Mr. Dobson, architect, Crewe, said five guineas was a very good price to pay for such a plan as the plaintiff had made. Judge Hughes gave judgment for the plaintiff for £5, which had been paid into court.

A refuge and shelter for women has just been provided in Paul-street, Liverpool. It consists of disused baths and wash-houses acquired from the Liverpool Corporation, and adapted for their present purpose from plans by Messrs. Ware and Rathbone, architects, of Dale-street. The works have been executed by Mr. G. C. Beesham, Brading-street, in the same city, at a cost of £4,000.

The Bishop of Dover visited Ashford on Monday for the purpose of formally opening the newly-erected parish-room. The side of the building next the College has, like it, oak timber framings and stucco panels, whilst the front facing the churchyard is of Kentish rag stone, with dressings to agree with the style of the church. Internally the rooms are faced with red brick, with a pinewood dado all round, 5ft. high. The main room is 55ft. by 25ft. with a raised platform at one end. The accommodation of the large room, exclusive of the platform, is for 220 adults, whilst the classroom will take 30 in addition. The windows are Elizabethan in character. The work has been carried out by Mr. E. Dryland, builder, of Ashford, from the designs, and under the direction, of Mr. R. Philip Day, 20, John-street, Adelphi, London.

WATER SUPPLY AND SANITARY MATTERS.

SEWAGE DISPOSAL AT SALE.—The Local Government Board has now approved of the scheme prepared by Mr. A. G. McBeath, surveyor to the Board, for the purification of the sewage of the township, and given its sanction for the borrowing of the money, about £19,500, necessary for the purchase of the land and the execution of the various works. The system to be adopted for the purification of the sewage is one of precipitation and filtration. The effluent will flow into the Mersey by gravitation. The sludge will be treated so as to form manure. The site of the works is near the Bridgewater Canal, and will cover an area of 5½ acres, but the total area to be acquired for sewage and other purposes is 15½ acres, leaving ample room for extension hereafter if necessary. The amount sanctioned by the Local Government Board will be borrowed for terms of years ranging from 15 to 50 years.

WEST HARTLEPOOL.—The sanitary authority is actively engaged in many schemes for the further improvement of the district, including sewerage works, street works, new abattoirs, &c. One of the most beneficial amendments, however, so far as the public health is concerned, is the new regulation in connection with the erection of new buildings, which requires that each new dwelling-house erected after the present date shall have a water-closet, together with a covered galvanised pan for the reception of the dry domestic refuse. Mr. J. W. Brown, A.M.I.C.E., the borough engineer, under whose supervision the new regulations have been made, has been a strong advocate for the water carriage system for many years.

CHIPS.

The Working Men's Club, Methley, has been ventilated throughout by Messrs. Baird, Thompson, and Co., London and Glasgow.

The local board of Bexley have decided to divide the offices of surveyor and inspector of nuisances, hitherto held by Mr. Boulter, and to retain the services of Mr. Boulter in the former capacity at £230 a year.

Alderman E. C. Patching has been re-elected for the second time Mayor of Worthing. His father, now in his 92nd year, still carries on business in the town as an auctioneer and builder.

In the last number of our paper, in a small paragraph about the opening of a mission-hall at Ashford, Kent, it was stated that Mr. P. Day was the diocesan architect. This, it appears, is not correct, as Mr. James Brooks, V.P. R.I.B.A., is the diocesan architect. So Mr. J. Martin Brooks writes us, and requests us to state.

A reading-room has just been provided for the two parishes of Warham All Saints and Warham St. Mary Magdalen, Norfolk. The building is situated in the former parish, and is built of white brick with red facings, being capable of seating over 300 people when the partition is opened. The architect was Mr. Arthur Reeve, of Westminster, and the contractor Mr. T. Platten, of Wells-next-the-Sea. Lord Leicester gave the ground and the bricks, and the rector found all other necessities at a cost of £500.

The premises No. 22, Silver-street, Durham, locally known as "The Durham Mustard Mill," are about to be considerably enlarged and altered by Mr. H. T. Gradon, architect, of Durham, for Messrs. Levy Bros., the owners of the property.

The infectious wards at the Dartford Union are being warmed and ventilated by means of Shorland's patent Manchester grates, the same being supplied by Mr. E. H. Shorland, of Manchester.

Another memorial window is just completed in Manchester Cathedral, being a new four-light window on the south side of the recently-erected baptistery, at the west end of the nave. It forms a companion to one recently placed at the west end of the baptistery, and, like the other, has been executed by Messrs. Percy Bacon and Brothers, of London. It consists of four lights, the subject treated being the Saviour in the act of blessing little children.

For some few years there has been a great dearth of cottage property in the Pontefract district, consequent on the extension of collieries in the neighbourhood. In many instances three and four families have been residing in one cottage, and there has been consequent overcrowding, and high rents. Two firms of builders alone have now on hand the erection of 300 houses, and 100 more are being built by private enterprise.

A committee has been formed for carrying out a cathedral memorial to Edward Harold Browne, the late Bishop of Winchester. The memorial is to be a recumbent figure of the bishop on an altar tomb, designed by Messrs. Bodley and Garner. About £1,500 will probably be required.

Our Office Table.

The annual address of the President of the American Institute of Architects deals largely with matters of constitution and organisation. It appears that the eastern chapters, owing to long organisation, have secured general recognition in New York and Boston, and the younger chapters are making themselves felt, especially in Illinois and Kansas City. The Boston chapter refers to the building law of that city. The Boston Society of Architects drafted the original building law, and one of its members was made one of the Commission of three appointed to draft a new law. To this commission are referred all statutes, fountains, and works of art placed in public squares, parks, or buildings in Boston. The President also refers to the Bill to License the Practice of Architecture, which failed to become law in the State of New York, and to the false idea which militated against the Bill, that it was the intention of its advocates that the license shall precede, and eventually annul, the building laws, whereas such a notion was unreasonable, as the license and building law is a reflex one of the other; the law an epitome of the licentiate, the licentiate a warrant of the law.

The one hundred and thirty-ninth session of the Society of Arts was opened on Wednesday, when an address was delivered by Sir Richard Webster, Q.C., M.P., chairman of the Council. Among the papers to be read this session are those by Mr. Seymour Haden, on "The Disposal of the Dead," on Wednesday next; Mr. James Douglas, on "The Copper Resources of the United States," on November 30; and Mr. James Dredge, on "The Chicago Exhibition, 1893," on December 7. At subsequent meetings, the dates of which are not yet published, papers will be read by Mr. William Key, "The Purification of the Air Supply to Public Buildings and Dwellings"; Mr. Wilton P. Rix, "Pottery Glazes, their Classification and Decorative Value in Ceramic Designs"; and Sir Juland Danvers, K.C.S.I., late Public Works Secretary, India Office, "Indian Manufactures." A course of Cantor lectures on "Some Masters of Ornament" will be given by Mr. Lewis F. Day, on April 10, 17, 24, and May 1; and another on "The History and Practice of Mosaics," by Mr. C. Harrison Townsend, F.R.I.B.A., on May 8 and 15.

The old church at Arbroath was destroyed by fire on Monday morning, nothing but the semi-detached tower and spire (both added in 1832) being saved. The church was built in 1580, partly with the stone of the Abbey, and was enlarged and partially reconstructed in 1762. It contained some excellent carved work in the pews and an organ erected eleven years ago. The church and its contents were insured for £3,900, a sum which will not cover the estimated loss. The cause of the outbreak is unknown.

A CURIOUS action between a contractor and a builders' exchange was lately tried in Pennsylvania. In Pittsburgh, last year, the building-trades unions struck, at the beginning of the season, for increased wages and an eight-hour day. The master-builders united to resist the demand, and, after three months of idleness, the men gave up the struggle. During the strike, many journeymen, members of the unions, set up as contractors, hiring men on the Union terms, instead of siding with the master-builders in the effort to resist the Union demands. When these new contractors tried to buy materials, however, they found that most of the dealers were members of the Builders' Exchange, and would not sell goods to any customers not members of the Exchange. This caused the new contractors loss, as well as delay, and one of them, a man named Buchanan, applied to the Courts for redress, setting the damage which he had suffered at 350 dollars. Buchanan's suit is simply a test case, and if the decision is favourable to him, many other similar suits will be entered. The case has now gone through the inferior court, which has given a verdict for the petitioner; but an appeal has been taken to the Supreme Court.

The Bishop of Peterborough preached at the parish church of Ashby-de-la-Zouch on Friday, and unveiled a memorial window by Messrs. Lavers and Westlake and dedicated a carved oak screen designed by Messrs. St. Aubyn.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Royal Institute of British Architects. Business Meeting. 8 p.m.
Society of Arts. Cantor Lecture No. 1. "The Generation of Light from Coal-Gas," by Prof. Vivian Lewes. 8 p.m.
TUESDAY.—Institution of Civil Engineers. Discussion on papers on Graving Docks. 8 p.m.
WEDNESDAY.—Society of Arts. "Cremation as an Incentive to Crime," by F. Seymour Haden. 8 p.m.

CHIPS.

Mr. James Lemon, J.P., F.R.I.B.A., M.Inst.C.E., has been re-elected Mayor of Southampton.

Mr. E. Stanley Holland has been appointed borough surveyor of Leominster.

The opening meeting of the Manchester Association of Engineering Students was held on Wednesday week, when Mr. Lionel B. Wells, M.Inst.C.E., the president for the current session, delivered his opening address.

The Governors of St. Thomas's Hospital, London, on Saturday applied to Mr. Justice Kekewich for permission to sell out Consols to enable them to raise £16,000 for the erection of a new medical school on the Embankment. His Lordship, while expressing himself in favour of the scheme, adjourned the application for certain formalities to be proved, saying a building contract might meantime be entered into.

It is satisfactory to be able to state that Mr. Tate has renewed his offer to present his valuable collection of pictures to the nation, and that the offer will probably be accepted within the next few weeks. The difficulty of finding a site for the new gallery has been almost surmounted, and it is hinted that the new edifice will be in the neighbourhood of Westminster.

New Sunday-school buildings were opened at Layerthorpe, York, on Tuesday week. The chief room is 46ft. by 21ft., with classroom 17ft. by 14ft. Mr. George Kidd, of Spen-lane, York, was the contractor.

A serious landslip has occurred at Clacton-on-Sea, a mass of the cliffs, weighing about 4,000 or 5,000 tons, opposite the first Martello tower, falling on the beach. With the cliffs went the remains of the small battery which stood between the tower and the shore.

A free library was opened at Leominster on Thursday in last week. A house in South-street has been acquired and refitted for the present purpose, from plans by Mr. F. R. Kempson, architect. The contractor was Mr. Henry Milward, of Leominster, and the work was carried out under the supervision of Mr. J. W. B. Rooke, the borough surveyor. The amount of the original contract was £900.

On Friday a new Wesleyan Chapel was opened at Dishforth, Boroughbridge. Mr. Stokes was the architect, and Mr. Jackson, of Thirsk, the builder.

The session of St. Paul's Ecclesiological Society was opened last (Thursday) evening, when a lecture was delivered by the Rev. G. F. Browne, B.D., F.S.A., Canon of St. Paul's, on "Christian Art in Early England" with lime-light illustrations.

The Board of Trade Journal gives a gloomy look-out of the condition of trade throughout the country, in the course of which it is remarked:—"The building and cabinet-making trades are the only industries that may be considered as at all prosperous, but the former branch of industry is gradually becoming worse."

The contractors for the extension of the Highland Railway, Messrs. Lucas and Aird, of London, began operations on Monday with the last section of the new through line from Inverness to Cullodich—that is, through the estate and battlefield of Culloden, and across the river Nairn, over which will be thrown one of the finest stone viaducts in Scotland—to the point where the Strathnairn contract, which is now being vigorously carried on, terminates. This part of the contract amounts to £117,295, and with its commencement the entire works of the new through line are now in process of construction.

At the last meeting of the London School Board, a long debate arose out of a recommendation from the Works Committee for the addition to the offices of the board, now being enlarged from Mr. R. W. Edis's designs, of a clock-tower and clock, at an estimated cost of £3,000. It was stated, in the course of the discussion, that £220,000 had already been expended on the offices and site, under three architects. Eventually the matter was referred back to the committee.

The Handsworth School Board, at their last meeting, decided to make several important alterations and additions to the Boulton-road schools, and appointed Mr. J. R. Nichols, M.S.A., architect, of 59, Colmore-row, Birmingham, and Handsworth, to prepare the necessary drawings and estimates.

FRIDAY, NOVEMBER 25, 1892.

"THE STICKIT ARCHITECT."

READERS of Scottish novels have often made acquaintance with the "stickit minister." Trained, up to a certain point, with the view of occupying a pulpit in the kirk, he has somehow failed to secure one. He may have been unfit, and he may even, in certain cases, have been too good. So it is with the "stickit architect," who is even commoner in England than is his ecclesiastical brother in more northern latitudes. On a large building committee there is sure to be a "stickit architect," under some disguise or other, and the stronger the reasons for which he stuck fast, the harder he is likely to be on those who are more fortunate. His fellow members consult him with the natural readiness of men who see the chance of getting professional advice without paying for it. When words of wisdom fall from his lips, they feel that they are the opinions of an architect, and they forget that they are the words of a "stickit" one. The result is that he receives more deference than he deserves, and that his power for mischief may be out of all proportion to his real importance.

A. was an architect of the partially-"stickit" type. He had begun life as a designer of gin-shops and a planner of small public-houses; and this, to some extent, he remained to the last. Experience showed him, however, that hard work was less profitable than hard swearing. In arbitrations and compensation cases there is a steady demand for witnesses, and the demand naturally produces the supply. Here was an opportunity for A., as there is for many others like him. When a railway company and a landowner differed about the value of a property to be taken, and when one side put it down at £50 and the other at £5,000, A. was prepared to give evidence supporting either party, as accident might determine. With an imposing presence and a profound faculty of adapting his views to the needs of his clients, he became a successful man. Hard swearing about the value of land and houses has money in it. Hundreds of people require it who never require architecture or art in any form, so that an unblushing witness with some professional training is worth his price. A. consequently became a prosperous man. He still called himself an architect, and people who did not know the nature of his business supposed him to be so. And he was not without some ambition to deserve the title. Now and then he engaged in a competition; and though he never gained one, he did on a certain occasion what answered his purpose even better. He was connected with the promoters of an important building; he submitted a design for it; and when his design was rejected, his friends consoled him by giving him a chief place on the committee. There is no need to detail his revenge. The position of the successful competitor may be imagined. His work was turned into a fight for life. If A. could not produce architecture himself, he had learned enough to know when anyone else was producing it, and he used his knowledge to much purpose. To every satisfactory point in the accepted design he was a deadly foe. He advised alteration after alteration, each more ruinous than the last, and finally he managed to deal his rival a blow on a matter of construction. He affected to believe that the lower part of the building was too weak to carry the superstructure. He got the

matter referred to an eminent architect, who had not seen the foundations put in, or the bottom of the very massive walling built. This gentleman had everything to lose if the work gave way, and nothing to gain if it stood fast, and he was supplied with calculations which made it seem weak where it was really strong. The natural result was that, without pronouncing against it, he did not speak of its strength with absolutely boundless assurance. A. seized upon this circumstance, worked on the fears of his fellow members, and got them to insist that the work should be, as he termed it, "strengthened" before it was carried any higher. His "strengthening" consisted in building up £200 worth of perfectly useless brickwork against the previously built walls. It carried nothing, it buttressed nothing, it was a mere dead weight on the foundations; for all the aid it gave to the building, it might as well have been put up in Patagonia or Kamskatcha. But it served A.'s purpose. It helped to discredit the successful competitor, and after that, when anybody remarked that he had erected a novel and, on the whole, "successful building," somebody else was sure to answer, "But don't you know he made the tower so weak that hundreds of pounds had to be spent in strengthening it?"

The "stickit" architect, however, does not always employ himself in trying to make other architects stick. There are good varieties of him as well as bad; and not a few "stickit" architects have possessed more ability than the majority of successful ones. B. was a man who gained competition after competition, and who gained them by undoubted merit—a man whose advice was sought, and whose criticisms were respected throughout his profession, yet he ended without a practice what might have been a most brilliant career. This was due in part to bad luck as well as to bad treatment. For one reason or other, his competition designs, though they gained the first place, were never carried out. When other men are victorious in struggles of this sort they are generally left in peace to execute the schemes they have devised. It was not so with him. Sometimes he merely received the first premium, while the plans which had obtained the second or third one were those actually adopted. Sometimes the competition fell through, and a second one was arranged, with the effect of excluding him altogether. The designs which he made for non-competitive works were admired, but not accepted; or if they were accepted, the building was pretty sure to be abandoned. The fates seemed to be against him. His own executed works scarcely amounted to half a dozen. He assisted more fortunate men, and his best ideas—sadly distorted, but still notable—went to build up the reputation of architects not worthy to be named in the same day with him. It was a melancholy and an exceptional case, not easily to be accounted for. His powers were far above the average; his faults were a tendency to underrate the importance of convenient planning, and an inveterate habit of calling a spade a spade. This last peculiarity involved him in quarrels with his clients, and they were not, as a rule, over-scrupulous about the means they employed in order to get rid of him.

It is pleasanter to remember in how many cases the "stickit" architect has grown into a successful man. One of the best, if not the very best, of living novelists was trained to our profession, and the truth with which, on occasion, he describes any feature of an old building which may happen to come into his story is startling from its contrast with the common literary practice. Amongst those who began as architects, but who did not long remain so, we may also name one of our best living poets, who, like some poets of the Italian Renaissance, has worked to

good purpose as a maker of other things besides rhyme. Painting has employed many a "stickit" architect whom she has had no cause to be ashamed of; the subordinate arts allied to our own have been almost brought back to life in recent times by men with an architectural training, and even the drama could ill have spared some distinguished performers who were recruited from our ranks. Why did men of so much ability leave us? No doubt there were many reasons. Architectural renown is a thing of slow growth, and some of them saw shorter cuts to fame. An architect, again, may live and die with his imagination full of grand ideas, which, for want of opportunity, have never been made public. It is of no use for him to dream of a cathedral, when his clients want a factory or a model lodging house: he must build what is needed, or nothing at all. The painter and the poet are not limited in this way. What is in them they can bring out; and their finest thoughts have not to lie dormant till this work-a-day world chances, if it ever does chance, to call for them. The artist, too, may be very strong in a man, and the calculator, the planner, and the constructor very weak. It is natural enough, in that case, that he should find more congenial employment in painting or decoration, or even in literary work. But wherever he may ultimately place himself, his short architectural career will have done him more good than harm; and he may finally see that it was an indispensable preparation for his success.

CLAIMS FOR FEES.

ACTIONS brought to recover fees for the preparation of plans and for superintendence often turn on questions of expense or negligence. No doubt these are the two chief points which architects have to mainly guard against in their dealings with clients. The plans submitted are too expensive to carry out for the sum which the employer proposes to spend, a fact which becomes evident when the tenders are received. Or the work is proceeded with, and the employer refuses to pay on the final certificate, on the alleged ground that the plans and specifications have not been properly carried out, or that the architect has failed from negligence, and his fees are consequently disputed. Two recently reported cases have shown the risks and liabilities to which architects are exposed. In one of the cases brought before the Newport County Court, an architect claimed for fees for plans and superintendence in the erection of houses. The defendants brought a counter-claim for alleged negligence on the part of plaintiff. The latter prepared two sets of plans, the first set being too expensive, and the new set was made for houses which were not to exceed £600 each. The defendants were, it would appear, satisfied with the new plans, and tenders were obtained, one of which was accepted. It is stated also the architect gave a certificate to the effect that "in his opinion the work was satisfactorily completed," but from the evidence reported it appears there was some doubt about this even in the plaintiff's mind, as he wrote to defendants saying he was willing to refuse to give a final certificate if the defendants would indemnify him against legal proceedings. Some time after a deputation from the Master Builders' Association waited upon him, and on the same day he gave his final certificate after examining the plans, specifications, and estimates. A subsequent report we have received shows that professional witnesses had confirmed the plaintiff's action in giving a final certificate. There were certain items in dispute, the thickness of the mullions of the windows, &c.; the evidence called for the defendants proved certain defects, and the Judge, after hearing evidence for the plaintiff, said that the plaintiff had given

his certificate improperly, and had altered his views. Judgment was given for the plaintiff for £12 11s. 6d., and also for the defendants on the counter-claim, evidence to be given as to the amount. It is needless to say anything on the merits of this case, the details of which are not very clear, except as to the importance attached to a final certificate. As far as we know, the defendants received full value for the money expended in the houses; and the evidence for the plaintiff proved that he had not been negligent. An architect is often in the difficult circumstances of being between two fires; his client looks to him to refuse a final certificate till every item of the work is fully complete; on the other hand, the contractor threatens to take legal proceedings against him if he declines to give one. The architect, of course, ought to be the judge in the matter, and use his full discretion under the circumstances. It does not answer to exhibit any vacillation. If he thinks the work is not fairly completed by a certain day according to the terms of the contract, he should refuse to give a certificate, even under threats. On the other hand, an architect must make up his mind to use sufficient discretion as not to appear to put any trifling excuse in the way of granting a certificate when he thinks the work is fairly complete. To establish a claim for fees, an architect has to be very cautious. He must be able to resist any counter-claim brought by the employer for alleged negligence, and therefore he must show that the work has been satisfactorily carried out to the full meaning and intention of the plans and specification, and especially that no defects of a serious kind exist. Unless he can do this, he had better pause.

In another case, at Crewe, an architect sued for fees amounting to £18 12s. for plans and sketches for a house that had been erected by the defendant from plans by another architect. There was some doubt as to the contract between the plaintiff and defendant. For the former it was alleged that he had taken plans for the defendant's approval, and at his request had made a sketch of a house at another place. The defendant had made suggestions for certain alterations, and fresh sketches were prepared, and levels of site were taken by the plaintiff. The defendant appeared satisfied, but subsequently employed a local architect, alleging that he thought he would give more attention to the work. Plaintiff was awarded £5 for his services. In this instance it was stated the plaintiff had called upon the defendant and asked for the job. The facts as reported require little comment. An individual who contemplates building is not indisposed to look at designs which may assist him to form ideas of his own. It sometimes happens that an architect has done something of the kind before which may be of service, and may feel very anxious to bring it to the notice of the person about to build; perhaps oftener it is regarded as a good "stroke of business" to introduce one's self. In country towns the practice is by no means uncommon; the plaintiff did as hundreds of others do, and his *quasi* client probably derived some advantage, and at least so far entertained the proposal as to ask the plaintiff to submit to him a sketch of a house, and made some suggestions which were apparently acted upon. All this trouble may, however, be sometimes thrown away upon an owner who has not quite made up his mind. At least, this much may be said generally as applicable to all such cases. An architect who calls upon a person unsolicited, and brings him designs he had by him for approval, cannot plead a retainer till some instructions are given to him, or certain acts done. Such a retainer would be found in any instructions given by the owner as to alterations, and it is upon such ground a

claim is often made. Many architects are in the habit of calling upon individuals who are thinking of building, and submitting plans for their inspection; but until they obtain any verbal or written instructions or requests from the owner, their services are likely to go unrequited—to say nothing of the professional etiquette of such a course.

ARCHITECTURAL ASSOCIATION.

THE second ordinary meeting for the present session of the Association was held on Friday evening, the President (Mr. H. O. Cresswell) in the chair. Messrs. O. G. Crockett, O. Little, J. Newnham, and G. H. Allison were elected as members.

SOME MYSTERIES OF MODERN ARCHITECTURE.

A paper on this subject had been written and forwarded by Mr. PAUL WATERHOUSE, M.A., who was, unfortunately, laid up by an attack of bronchitis, and was, therefore, read for him by the President. The author said he proposed to look at some of the points relating to architecture and its relation to other arts. The prefatory question, "What was architecture?" was not a conundrum; if it were, there would probably be an answer to it, but there was not—at least, there were several replies, which, for logical purposes, came to the same thing as leaving the question unsolved. The best reply was a negative one, showing what an architect was not. An architect was not a man who was ignorant of the principles of construction or of the elements of drawing; he was not a man who knew nothing of the history of great buildings in the past, nor of the requirements of wholesome buildings at the present; he was not a man incapable of comprehending the ingredients of design. Here was the *raison d'être* of such tests as architectural examinations. A great many of the enemies of examinations, and possibly some of their warmest but not wisest friends, considered that they were regarded as conferring, when successfully passed, a diploma of qualification. This was a great mistake, for examinations were not a golden key, but a sieve. If a man squeezed through he showed that he was not of so gross a clay as to be absolutely unfit for the function in life to which he aspired. But to say that all who successfully passed these examinations were thereby duly certified as complete and efficient architects, was, under any system of examination, impossible. It might be said by some that an architect, like a poet, was born, and not made; but it was of some practical necessity even to a poet to be taught a language and the use of A B C. As to the controversy, was architecture an art or a profession? if either of these terms could be logically defined, which the author doubted, architecture would be found to be both. A tenet in Greek philosophy proclaimed that man was a compound of the beast and the god. Were he purely divine or purely animal he would cease to be man. This analogy applied to architecture, which was allied, on the one hand, to the fine arts, and on the other to those industries whose function was to supply the apparatus of life and comfort. One of the first duties of architecture was to minister directly to the physical requirements of man. It had an element in common with all other arts, namely, the undefinable but well-understood element that it was an art; but its first, or normal, function was the application of that element to the otherwise purely utilitarian process of providing man with a dwelling. It was sometimes said that there were two kinds of buildings: those that had architects and those that had not, and it had been contended, even by a well-known authority, who ought to have known better, that an architectural building differed from a non-architectural in being, among other things, more costly. But the author contended that every building required, and for that matter had an architect. The architect might be consigned to oblivion under the guise of a salaried (perhaps a low-salaried) clerk in a speculative builder's office, or he might be reft of his credit by a usurping client, who said: "I designed my own house, you know; just got a draftsman fellow to put things together, but I settled it all myself." But for all that, some one brain must conceive and contrive the building, or as an edifice it would suffer, if only through the waste of material. It being conceded, then, that every building, however small and cheap, had an archi-

tect, buildings might be divided into three broad classes. In the first class were the buildings best described as monumental. In the next were the domestic (use the term widely), and in the third the utilitarian, which had to fulfil a useful end at the least possible outlay, and it was not derogatory to R.A.'s that dust-bins and pig-sties had been designed by members of the Royal Academy. The highest class—the monumental—in the scale contained buildings of public importance of all kinds. In these it was of prime importance that the details of the architecture should conform to a recognised style; and for this reason it was generally allowed that they should be produced by men who had made a professional study of style. In the intermediate class—the domestic—a greater liberty was allowed in the matter of design, and, alas! still more liberty was often taken. It was in this class of work that the public most readily adopted the error that an architect's building means a building in the construction of which they paid a professional gentleman to make it more expensive than it need be. An architect in this aspect ought to be one who combined the artistic and economic arrangement of his client's wants. The client stated his requirements, the architect solved his problem, or he had also to enlighten his client as to what was really wanted, or what he ought to want. There was a fourth class in which a wealthy client gave absolute *carte blanche* to the designer. Most architects longed for opportunities of this kind, but until they came he doubted if they realised the blessedness of the restrictions under which they usually worked. Restrictions were not the curse, they were the blessings of architecture, and here was one of the mysteries of architecture. If a client removed all restrictions, what was to be done? Why, it was left to the architect to make his own, and then they saw what stuff he was made of. Where would he admit, and where omit enrichment? Where would he extend, and where compress his accommodation? Where would he use his costly materials? Where would he decide that they were out of place? Where would his elevations be exuberant? Where would he keep them quiet? Nothing could guide him but his artistic sense, and if this were absent, the architect would succeed, no doubt, in assisting his client to break a record for outlay; but would he, by virtue of his opportunity, have been able to put himself ahead of his brothers in art who were not blessed with such liberal patrons? It was a melancholy fact that few would show their best talents in a case of *carte blanche*. Passing on to consider another point, Mr. Waterhouse asked whether the best architects were those whose works were most appreciated by the general body of the enlightened and educated public, an inquiry which he thought must be answered in the negative. He would go further and assert that at no period was there an intelligent public taste in architecture, not even in the 13th century or in the best period of Greek art. For example, in the many works that remained to us of the general and philosophical literature of Greece, there were nothing more than general allusions to architecture, and hardly any references to these principles which underlaid its successful development in the country. Take Plato and Aristotle, writers who made it their very business to analyse the arts and their functions; what had they to say of architecture except in the most vague and general way? Until in the writings of the great thinkers of Greece they could show some evidence that they knew more of architecture than the difference between Doric and Ionic—then and not till then would they be able to entertain a belief that the very considerable intricacies of the seemingly simple Greek architecture were the more or less common property not merely of recognised specialists, but of the general body of citizens. But even, Mr. Waterhouse continued, any exceptions, and even the rare instances in our own country of amateurs who become architects, sometimes to the great disadvantage of the art with which they thus coquette, will not disprove the general truth of the statement that in all ages, even in those where by some coincidence the public taste encourages for a short period the really best class of work, and perhaps, especially in the present day, architects have not dared and do not dare, to listen for approval or for condemnation to the public voice. When we sit at our drawing-boards, using alternately india-rubber and pencil over some half-developed elevation, to whom is it that in our inmost

consciousness we appeal as arbiter? To our own eye in the first place; perhaps (and this is a fallacious, but not unknown, tendency in the case of competition works) to the supposed taste of the assessor, and often to the general body of our professional brethren, present and future; in many happy instances we have a thought of our clients' approval, but of the public taste—never. But, after all, it will be argued, it is the public who choose architects, and consequently it is the public who decide to whom shall be given the greatest amount of work. They sometimes call, in cases of competition, a member of our own profession to assist their selection, but even in these cases they reserve the right to fall back on their own opinions as to which of the competitors supplies the best design. This is one of the mysteries, not of modern architecture only, but of our profession at all times. Our beginners have not the same opportunities of starting practice on their own merits that are accorded to novices in other arts. The young painter and the young sculptor making experiments at their own expense, and with a comparatively small outlay, chiefly of time, by means of exhibitions acquire the notice of the public who are to become their employers. But what can an architect student do to win the confidence which is so slow in coming? He can compete for architectural prizes—that is, for the rewards annually offered for designs on paper; but success in such competitions, even if it implied (which it does not) the power to bring an actual building to successful completion, is not equivalent to notoriety. A place—even a place near the ceiling on the walls of the Royal Academy—is a better thing for the commercial prospects of the budding painter than the winning of the Soane Medallion, or even the Academy medal, is to the professional welfare of an architect, though it represents a lower stage in the range of art. Architects have to make their beginnings, and even to practise their failures at other people's expense; and thus, unless an untied man wins a competition, or has a little spare cash with which he can build himself a suburban residence as a sample, he has nothing but drawings to show as specimens of his capacity. In other words, a painter or a sculptor gives the public some security, some guarantee. The architect, on the other hand, asks his first client to spend without security, and even if he were to forego the amount of his commission, this would not, in the event of failure, compensate the client for his outlay upon the building which had gone wrong. And now allow me to conclude with a few reflections on that most mysterious matter, the matter of progress. It is obvious that we architects differ very greatly from one another on the very ground that we often take widely different views on this very vital question—the aim of our art. To some men, clearly the idea of progress represents origination in the form of novelty. Architecture in their eyes is first and foremost a creative and an inventive art, and they resolve to mark their own footprints by casting aside the things of the past, and by being original at any cost. Another school, realising the daily advance in our scientific knowledge, and the consequent increase in our acquaintance with the properties of materials, feel that architectural progress is embodied in the adaptation of the needs of a building of all the newest opportunities which an ever-broadening science lays at our command. A third group, feeling that architectural beauty is largely a matter of association and tradition, look to a complete knowledge of some phase or phases of extinct art as the true solution of our modern problem. Hence we have side by side three bodies of workers, differing not merely in the degrees of capacity, but in the radical divergence of their views on the fundamental aim of their work; there may be three men, all honest workers, all men of talent, all men of moderation—one will be a pioneer of originality, one a leader in constructional novelty, and the third, stickler for precedent; there may be three others who are failures, but on the same lines of classification—one an outrageous innovator, and the other two respectively a hopeless utilitarian and a barren antiquarian. Each has only to accelerate his pace to accelerate his ruin. Is, then, the mystery of progress in architecture insoluble? I think not; but we had better help ourselves to its consideration by another appeal to a metaphor—to the metaphor of language. The whole art of language is not to produce one class of composition only; but it is rather an intel-

lectual equipment, fitting its possessor for a variety of productions in various departments. Thus it is with architecture. While in every individual design the architect has a particular object in view, the art, as a whole, has a different, a wider, a more general object, the achievement of which is the aim of the art, and the road to which is the road along which progress is marked. Architecture is a means of expression, in which we have both poetry and prose; and the prose, as in literature, may be dignified no less than the verse—in fact, to be good prose it must be dignified. The purpose of architecture is expression—genuine expression; generally serious, not always solemn, but never flippant; and thus the aim of architecture is facility of expression in whatever mode the particular case demands; and in so far as this aim is approached progress is obtained. And what is the recipe for this royal road of progress? First, study of past methods; secondly, study of present needs; and, lastly, practice. Our own motto is a worthy guide—"Design with Beauty, Build in Truth"; but our motto is of little use to us if we have no means of asking and answering the questions "What is Beauty?" "What is Truth?" Our art has many mysteries—not fewer to-day than in the days of old—and these mysteries, if we wish to know beauty and truth, are worth something more than an evening's consideration.

At the close, votes of thanks were accorded to the author and reader of the paper, on the motion of Mr. LEONARD STOKES, seconded by Mr. F. R. FARROW, and supported by Mr. HAMPTON W. PRATT.

EXHIBITION OF DOULTON WARE.

AT Messrs. Doulton and Co.'s show rooms, on the Albert Embankment, the memorial statue of the late Professor Fawcett, M.P., presented by Sir Henry Doulton, to be erected on the site of "The Lawn," Vauxhall Park, where the former Postmaster-General resided, is on view. The group, of terracotta, has been designed and modelled by Mr. George Tinworth, and has a total height of 16ft., including the pedestal, which is 7ft. 6in. high, and 8ft. by 4ft. at the base. The figures are of colossal size. Professor Fawcett is represented seated on a chair of Greek type, in academical robes; behind him is a figure of "Victory" with wings extended, holding a wreath over the head of the politician. Round the four sides of the pedestal are eight bas-relief panels of figures in terracotta, emblematical of Professor Fawcett's career. In the narrow side in front is "Courage," in the rear "Justice." On each side are three panels, representing on one face of pedestal, "Sympathy," "Courage," and "Truth," and on the other, symbolical of his work as Postmaster-General and Indian affairs, "Receiving Good News"—a female Post-office clerk—"Receiving Bad News," and "India." The likeness of the political economist is good, and the attitude meditative. The terracotta group in a buff tint is rendered more agreeable by the variety of warm tones due to the firing.

Not the least interesting part of the exhibition is the splendid collection of objects of Doulton ware, Lambeth faience, Burslem china, Carrara silicon, and other art productions intended for the Columbian Exhibition at Chicago, displaying the resources, technical and artistic, of Messrs. Doulton's potteries. We can only mention the fine vases in Lambeth faience painted by Miss Florence Lewis, unfired, in which palms, cacti, and other plants are introduced of a rich yellow ground; a pair of Doulton vases on pedestals, with etched designs of horses round the bodies, painted by Miss Annie Barlow. The magnificent pair of ewers in Doulton ware by M. V. Marshall are extremely elegant in design, and of a free decorative character in the modelling and colouring. Another pair of vases of bold folial design, with eagle handles and lizards in relief round the neck, and a centre vase of ewer shape by M. V. Marshall, are remarkable for their boldness and originality of conception, and the rich browns and blues of the material. The Perseus and Andromeda vase, with underglazed painting by Mr. Eyre, may also be noticed. A splendid case of Burslem china is on view. The double Goethe vase, representing Marguerite and Mephistopheles, is a dexterous and clever illusion, the former being always accompanied by the latter, which is reflected on the mirror. Some exquisite pieces, painted with animals and birds by G. White,

Wilson, and Mitchell, are amongst them. Mr. G. Tinworth's vase, illustrating the history of England, is clever. We also draw attention to a few painted panels by Esther Lewis and John Eyre, particularly to a figure of angel for church decoration designed by Mr. J. F. Bentley, painted by Mr. McLennan, in a dry impasto style, excellent in colour; and to a case of Crown Lambeth ware, containing some very beautiful examples of painted vases, and some charming figures of children in picture panels by Miss Dennis. The collection is well worth a visit by all lovers of artistic faience and pottery.

THE DUDLEY GALLERY.

THE New English Art Club has opened its ninth exhibition this week in the old Dudley Gallery connected with the Egyptian Hall, and the work shown, though marked by the same extravagant character, is by no means so interesting or so numerous as on some former occasions. Many of the studies have been intentionally made to fit old worm-eaten and dirty gilt frames, the key of the subject being so rendered as to harmonise with the decayed frame to which it has thus been adapted. The canvas-covered, mud-bedaubed frames of previous years are growing out of fashion seemingly with the members of the New English Art Club, and, consequently, old frames are likely, in confined centres, to be at a premium. However Mr. John Ruskin can bring himself to exhibit a drawing ("Dawn-Coniston") midst such a medley is past our comprehension, after his uncompromising attack, some years ago, upon Mr. McNeil Whistler, who here may find many excessively poor imitators.

Some of the pictures, if such they deserve to be called, are clever enough in the matter of trick and oddity; but for grace of drawing, beauty of colour, or healthy vigour of design, hardly one merits mention, where capable aspirants after fame have gone wrong in their impatient revolt against the pot-boiling propriety of popular picture-painters of the Horsley and Frith school. Wanton ugliness and insipid caricature are, however, no substitute for true art appreciation; and high prices asked for hastily-dashed-off rough pallet-knife studies, do not make these productions lasting or living works of art. "Boulogne Sands," by Mr. P. Wilson Steer, in pastel, is figured at 50 guineas, and a similar sum is asked for his "Procession of Yachts." Miss A. Holland's "Brown Study" (also a pastel sketch), modestly marked at £6 6s., on the other hand, is good in drawing, harmonious in colour, true to nature, unambitious in aim, moderate in scale, and hung up so that it cannot be seen as it deserves—an oasis in such company, though merely a study of chairs and a table. Mr. Fred Brown has a lumpy landscape, with clouds actually modelled in oil colour; but for dexterous blending of reds, his portrait model study, called "June," has no equal in the gallery. The roses in the air are introduced regardless of anything save colour, and the massing of the dishevelled auburn hair of the girl, put on with the knife, is wrought with the same idea. The red of the frock completes the harmony. The same model serves for a more ambitious work by the same hand, called "Penserosa," but which is not a success, except for the handling of the blue delf ware on the chimney-piece. The crane tile panel behind the girl gives her an *en bon point* appearance. "Lingering Light" is a golden landscape, studied for tone, by Mr. Moffatt P. Lindner; and "The Chrysanthemum Girl," by Mr. R. A. Bell, shows a dancing fairy, incongruously surrounded by isolated flowers. Miss Barber's "Swinehard from Hans Andersen" is much more really unintentionally funny than Mr. Arthur Lyard's panel design, called "The Crime," which is conceived as "a grotesque," intended for execution in wood. It is suitable for neither. "Rain in the Heavens and Geese in the Pond" is the title of Mr. Francis Bate's £50 landscape—a curious price for a curious picture. It looks more like the map of a country. In a case are shown some silver-work from the Guild of Handicrafts.

ROBERT BOYLE AND SON, LIMITED.

THE seventh annual general meeting of this company was held at the City Terminus Hotel on the 16th inst., when a dividend of 12½ per cent. was declared, free of income-tax, for

the year ending September last, after placing to reserve fund one-sixth of the profits earned, and carrying forward £1,386 4s. 9d. This makes the seventh dividend, 12½ per cent. being paid for the last three years, and 12 per cent. for the previous years.

Mr. ROBERT BOYLE (chairman and managing director), in moving the adoption of the report and accounts, which were unanimously passed, in the course of his remarks, said: You have now before you the results of our endeavours to promote the interests and extend the business of the company. I am happy to state that the orders and contracts secured during the year, especially in England, are considerably in excess of the previous year, though that was the most profitable year since the formation of the company. We have also at present in hand a number of important contracts at home and abroad, including the largest ventilating contract we have ever received from the British Government, and one of equal magnitude for the Spanish Government. Though we have a registered capital of £120,000, it has not been found necessary to call it all up, and I do not think that that necessity is ever likely to arise, as our reserve fund, to which a sixth of the profits has been added each year, is now represented by a substantial and solid sum, and is a sure guarantee against all ordinary contingencies. You will be pleased to hear that it is anticipated that the dividend for the current year will balance the subscribed capital of the company, including the ordinary shares held by myself, when cent. per cent. will then have been paid. As the holder of over three-fourths of the share capital of the company, to which I have added as opportunity offered, I think I need hardly say that, personally, I am perfectly satisfied with these returns, which we have been enabled to attain through a constant study of, and careful attention to, the requirements of our clients, and by the improvements which have from time to time been effected in our ventilating appliances, especially the air-pump ventilator, the improvements protected by our latest patent having not only added considerably to its power as a foul air exhaust, but rendered it entirely free from down-draught and perfectly noiseless—a most important point. The ventilator is also made of a more ornamental character, of the best rolled steel plates, galvanised and enamelled, and though it is in every respect superior to all previous forms, it is now supplied at a reduction of 50 per cent. on our original prices, constituting it not only the most efficient and ornamental, but the cheapest ventilator in the market. It has always been our aim to bring a really reliable ventilator within the reach of all by selling it at the very lowest possible price consistent with the best workmanship and material, and it is only owing to the very large and ever-increasing business that we are now doing that we are able to supply our ventilating appliances at the prices we do. I regret to say that the profession of ventilation-engineering is being brought into no small disrepute through the deplorable conduct of certain unscrupulous persons, who attempt to foist upon the public utterly worthless appliances, the failure of which causes all ventilating and sanitary arrangements to be looked upon with suspicion and distrust, retarding the advancement of sanitary science, and bringing it and its professors into discredit. Architects, from the special knowledge they possess, are, of course, not so readily imposed upon, as they are in a position to discriminate between the counterfeit and the genuine; but the general public, who are inexperienced in these matters, and prone to believe that they are getting a bargain when they buy an article at a low figure that would be dear at any price, are but too liable to be misled by the specious and mendacious assertions which are made by these harpies respecting the merits of their particular contrivances and demerits of all others, not scrupling to resort to the most unprincipled practices to accomplish their ends. It is a pity, especially for themselves, that these misguided people are seemingly incapable of realising that after all honesty is the best policy in business, as in other matters. It has been found necessary during the past two years to make certain changes in our staff, which, I am pleased to say, have materially conduced to the more efficient conduct and welfare of the business, and enabled me to devote more of my time to the development of the company's interests abroad. My latest tour through "the East and Australasia" has been, as you are already aware, very successful, this being the fourth time I have

circled the globe with the object of promoting an increased interest in sanitary matters, and securing the adoption of improved sanitary arrangements. A narrative of the tour has been published in book form, entitled "A Sanitary Crusade through the East and Australasia," and concerning which I have received, expressing their cordial approval of and sympathy with the work we are engaged in, a large number of letters from distinguished people—leaders in the scientific, literary, and political worlds, including a most encouraging autograph letter from Lord Salisbury. The London and provincial papers have also, in a very public spirited manner, referred to the evils described in the book, and strongly urged the claims set forth therein for their alleviation and redress, all of which will doubtless bear good fruit in the future. Of course, our work in its connection with the health and consequent welfare of the people is of a strictly practical and business character, and we make no pretensions to disinterested philanthropy, which, to be of any permanent value, should, I think, be at least self-supporting; still, it is always pleasant to feel that whilst we are promoting our own interests, we are also conferring substantial benefits on others. In addition to the agencies already existing, and which we now have in practically every country in the world, I have during my recent tour established agencies in Burmah, Queensland, New South Wales, Victoria, South Australia, and New Zealand, and completed arrangements for the manufacture of our different ventilating and sanitary appliances in each of the colonies. Scientifically applied, automatic ventilation is now being, as elsewhere, generally adopted in the colonies, plain, open pipes and mechanical ventilation having been found to be as great a failure where employed as they have proved to be in this and other countries, of which the system in use at the new London Law Courts is a notorious example, though all that money and skill could do to make the mechanical ventilation a success has been tried. I have surveyed and submitted plans and estimates for the ventilation of the new Jubilee Hall, Rangoon; King of Siam's Palace, Bangkok; Government Buildings and Museum, Batavia; the Chicago Exhibition Buildings; Houses of Parliament, Centennial Hall, Municipal Buildings, new Hospital, and new Theatre, Sydney; Houses of Parliament, Stock Exchange, Commercial Bank and Bank of Victoria, Melbourne; also for the complete ventilation of the new drainage scheme, Melbourne. At Adelaide the new air-pump ventilators have been applied to the Houses of Parliament, Government House, Government Buildings, Supreme Courts, Post-office, Hospital, Art Gallery, Museum, University, and other public buildings. At Christchurch, New Zealand, the house drainage is exclusively ventilated with the air-pump ventilators, there being over 5,000 used for this purpose alone. Several thousands are also employed for the house drainage at Wellington, the air-pump ventilator being also applied to the Houses of Parliament, Government House, Government Buildings, Post-office, Supreme Courts, Hospital, Opera House, &c.

The retiring directors and the auditors having been re-elected, a cordial vote of thanks was proposed to the board for their services, and to Mr. Boyle for his admirable management of the company during the year. This was carried unanimously, and a vote of thanks to the chairman for presiding terminated the proceedings.

PUBLIC BATHS AND WASH-HOUSES. —IV.

By R. OWEN ALLSOP, Architect.

Author of "The Turkish Bath," and "The Hydro-pathic Establishment and its Baths."

SWIMMING-BATHS.

ON the 27th May, 1878, was passed an amendment to the Baths and Washhouses' Act authorising commissioners to erect and maintain covered swimming-baths at the maximum charges to bathers of 8d. first-class, 4d. second-class, and 2d. third-class. The popularity of the public swimming-bath has continued to grow, and with it size has increased. Baths considerably over 100ft. in length are now frequently required. The large swimming-bath at the recently opened Hornsey Public Baths is 132ft. by 40ft., while the women's bath is 75ft. by 25ft.

The popularity of swimming-baths, having made them a remunerative feature in public bath-

houses, has enabled commissioners to afford good accommodation. By contrast to the newest bath the older swimming-baths seem frequently very inferior. Several are a disgrace to London.*

At some of the older London baths—as Kensington and Marylebone—three classes of swimming-baths are provided. A better arrangement is two classes only, and, if there be a small, third bath, let it be for women. The second-class bath will be smaller than the first, and the women's bath again smaller than this.

Baths over 100ft. in length afford a good swim, but a width of over 40ft. is not desirable. An undersized swimming-bath is a very useless thing. As to depth, all practical purposes are served by baths giving a water-depth of from 3ft. 6in. to 7ft. for men, and from 3ft. to 6ft. for women.

The hall in which the swimming-bath is constructed must be so much wider than the bath according to the arrangement of the dressing-boxes, &c. The space required from the edge of the bath to the face of wall cannot be less than 7ft., and 7ft. 6in. and 8ft. are better. The depth of dressing-boxes will require to be 3ft. 6in. or 3ft. 9in., and the gangway in front must be 4ft. 6in. wide. A bath 40ft. wide, with a row of dressing-boxes on either side, therefore requires a hall 56ft. wide, although 55ft. may do. The length of the hall will depend on the arrangements made. If there be a row of dressing-boxes at one end, and the other end be left unobstructed—as is usual, and most convenient—a bath 100ft. long will require a length of hall 114ft., which will leave a 6ft. gangway at each end of bath for diving stages, toilet places, &c.

The dressing-boxes of a first-class bath will be 3ft. 9in. square in the clear, or of a width rather under 4ft. from centre to centre of wood partition. The second-class dressing-boxes are frequently made somewhat smaller.

In one or more of the angles of the hall are commonly placed the sanitary conveniences; but in many baths, when thus situated, they have been found a nuisance, and been removed further out of the way. The Richmond baths are a case in point.

In some first-class baths a cold shower bath is fixed for use of swimmers. A warm, or hot one would be more reasonable.

Most first-class baths are now required to have good galleries for the public on occasion of swimming entertainments, &c. They are generally carried on rolled iron joists as cantilevers over dressing-boxes, and continue usually round the sides of the hall. A strong balcony railing is required.

The diving-stages or spring-boards are placed at the head of the baths, and are made in various forms. The supports are mostly of cast wrought iron, and the boards of oak or ash, with slotted eyes, and covered with cocoa-nut fibre matting, to afford a foothold to the divers.

The more light and ventilation that can be gained in the swimming-bath the better for both comfort and appearance. A long ridge skylight is the first requisite, and clerestory windows are very much to the cheerful appearance of a bath. A movable light in either of the end gable walls is very useful for ventilating purposes.

The proper material for roofs of swimming-baths has been a matter of some discussion. Wood has been used with good effect; iron has been employed with economy. On wood there is less condensation; iron is cheap. It is a matter, apparently, of individual choice.

In excavating for swimming-baths it has been suggested that the excavation should at first be only with the side walls of bath, and after the walls have been erected the "cake" should be taken out, and the floor of the bath put in. Every architect is at liberty to employ methods that most commend themselves to him; but nine out of ten practical constructors would follow the usual system. It is a great thing to get rid of the mess of excavating before commencing building operations.

Swimming-baths may be constructed wholly

* Those at Endell-street, Bloomsbury, for example, are as bad. Since the low prices of the baths the public establishments prevent private enterprise from flourishing, it becomes the duty of bath commissioners to see that good first-class swimming accommodation is afforded. Proprietors of private swimming-baths cannot keep high-class concerns going at the low prices of public baths. The fine floating "Cleopatra" swimming bath off the Thames Embankment was closed shortly after it was opened—presumably from the cause stated. Many swimmers must thus have been deprived of their bath, and if they found the accommodation of the nearest public baths very inferior, they would have just cause to complain of the working of the Act of Parliament.

0 5 10 15 20 25 30 35 40 45 50 feet

concrete, or with concrete bottom and brick-in-cement side walls. In any case glazed bricks will be required for the face, and bricks glazed on the flat side form a good bottom. The main work should be executed in a pure, white-coloured brick. Ornamental bands are generally introduced, and a few dark bands along the floor of bath, in the direction of its length, are useful as a guide to divers.

There is, of course, great pressure and weight

of water in a large swimming-bath, and the floor and walls should be proportionately stiff. On bad soils much concrete is required for bottoms, and the foundations of side walls should be spread out considerably in two or more setts-off. On pp. 49, 50, and 51 of "The Turkish Bath" are description and plans of a plunge-bath constructed with horizontal and vertical courses of asphalt to prevent leakage. The same construction is applicable to a swimming-bath, and, indeed, has

been successfully adopted at the new baths at Goose-green, Dulwich. The bottom and the side walls of concrete and brick-in-cement respectively are first constructed, and the whole surfaces carefully coated with asphalt, care being taken that open seams and joints in the asphalt are not left to defeat the end of the process, viz., the prevention of leakage.*

* I am told that the majority of London swimming-baths leak more or less.

Some constructors will put the concrete bottom on puddle clay, and puddle behind the side walls. A better way is to rely on a good thickness of concrete, and well-laid, sound brickwork, or the stratum of asphalt advocated above. A bath constructed with good cement concrete bottom, and with side walls of good thickness, and faced with glazed bricks in cement, should not leak to any noticeable extent.

The bottom of a bath slopes from the shallow to the deep end, but the foundations of the side walls should be stepped in three or more steps. It is customary in this country to make the slope of bath even from end to end. Some Continental baths have a sinking of considerable depth at the deep end, as at the bath-house in the Wienstrasse, at Vienna. Figures of the depth of some of the German swimming-baths show a surprising depth at the deep end, and this is accounted for by the fact that there is a sudden dip in the floor of the bath and a deep pool formed for bathers. Such a device, however, is dangerous where there are non-swimmers or indifferent swimmers in the bath.

The sides of a good swimming-bath are vertical. Baths have been constructed with steps all round—as Brill's circular bath at Brighton—but the customary arrangement is here the best. Solid steps into the bath, too, as formerly adopted, have given place to detachable wooden steps.

BUILDERS' EVIDENCE BEFORE THE LABOUR COMMISSION.

AT Tuesday's sitting of Section C of the Labour Commission, which deals with building, textile, and miscellaneous trades, Colonel Stanley Geo. Bird, Mr. J. Mowlem Burt (of Mowlem and Co.), Mr. G. Grover, Mr. H. J. Wright, and Mr. J. H. Bridgman, representing the Central Association of Master Builders, gave evidence in contradiction and explanation of statements made to the Commission by representatives of the workmen. The suggestion that there was no Government inspection, said Mr. Mowlem Burt, was incorrect, as the inspector visited his works once or twice a year, and had in one case ordered him to put up fencing to protect the men against danger from machinery. Also, it was not true, as had been stated, that the men might be employed more regularly if the employers cared to do so. It was always the interest of the employers to keep the men at work, especially the good workmen. It was denied that trade-unions in the building trade did not admit into their ranks a man unless he was a thoroughly qualified workman. While members of the unions readily complied with the orders of these organisations to go on strike, they did not always obey instructions from the same source to return to work when disputes leading to rupture were referred to the associations of the parties, and settled by them. There was not between employers and employed in the building trades the cordiality which should exist. The men were still animated by a desire to get all they could.

Mr. Mundella (the Chairman): I suppose the employers also have a desire to get all they can? Mr. J. M. Burt: Yes; but I do not think the feeling is quite so extreme among them.

Colonel Stanley Bird, in reply to Mr. Mundella as to whether there was not a good deal of inferior building in London, said that in regard to buildings which were erected under contract with an architect and a clerk of works "scamping" did not go on; but in the case of speculative building, which was only subject to the supervision of the district surveyor, there was no doubt that it did prevail. In the West-end of London there were a good many buildings which, after a dozen years or so, almost wanted rebuilding; but such were "jerry built" by speculative builders for the purpose of letting. He complained that trade-unions, by insisting on a minimum wage to workmen whether good or bad, dragged all men down to a dead level, and said that now that the London County Council and other public bodies were undertaking their own building operations, the master builders would soon have to come to a stop. The allegation that master builders were careless of the lives of their workmen in consequence of being able to insure themselves against accident, he said, was untrue. As to the proposed inspection of scaffolding by a State inspector, he said he would rather that the responsibility should be thrown upon the men, because they

would have a personal interest in seeing that it was safe. At his own works notices were posted asking the men to assure themselves that the scaffolding and plant were in good condition, and stating that notice should be given to the employer if anything defective were discovered. Mr. Mundella pointed out that it was practically impossible for every individual workman who was employed on a large job to see that the scaffolding was entirely sound. The witness, continuing, said that a workman did not do half the work now that he formerly did in an hour, notwithstanding the increased wages he received and the greater purchasing value of those wages. A bricklayer would formerly lay 1,000 bricks in a working day of ten hours, but now a man will not lay more than 300 to 400 bricks in a day of nine hours. The letting of brickwork was now at 90s. a rod, instead of from 30s. to 40s., and in the joinery trade from the same cause it cost as much now to produce the same work by machinery as when the men had to do the whole of the work by hand.

Mr. G. Dew, of the London Building Trades' Committee, and Mr. F. C. Burton, a member of the Strike Committee of Carpenters and Joiners, detailed the circumstances of the late strike in the London building trades from the men's point of view, alleging unreasonableness on behalf of the masters in refusing to meet the men, though they admitted that the first definite offer of arbitration came from the masters. Asked if they were willing, on behalf of the men, in the case of any future dispute to refer the matter to an equal number of representatives of each class with an impartial arbitrator, Mr. Dew said he should not like to say so, as the workmen felt they were so terribly sold in the last arbitration, though personally he had no fear of the result if the arbitrator was an impartial man.

A NEW WORKS DEPARTMENT AT THE LONDON COUNTY COUNCIL.

AN important departure was resolved upon by the London County Council on Tuesday after a long and animated discussion. A report was submitted by the General Purposes Committee recommending the constitution of a new Works Department, to consist of fifteen members, of whom one would be chosen from each of the existing committees, and there would be elected by the Council. It was recommended that to this new department there should be intrusted the present duties of the Stores Committee as to the purchase of articles required for general use, and in addition thereto the whole question of purchase and storage of plant and materials required in the execution of works and the general superintendence of all stores and store-keeping at the various depots in the Metropolis. To these also would be added the new duty of carrying out the works resolved upon by the Council. Under the proposed new standing orders every committee recommending the execution of any works should state whether they propose that the works should be executed by a contractor or by the Council, without the intervention of a contractor, and, if the latter course were recommended, they should lay before the Council full plans, specifications, and estimate of cost of the proposed works. This standing order would not at present extend to works of ordinary maintenance or repair. When the Council resolved to execute any works without the intervention of a contractor, the plans and specifications should, it was submitted, be referred to the Works Committee. If either the plans, specifications, or estimate of costs appeared to be inaccurate or insufficient, the matter would be referred back to the originating committee to bring up amended particulars. So soon as the Works Committee were satisfied as to the accuracy or sufficiency of the plans, specifications, and estimates, they would proceed to carry the works into execution. The Works Committee were to raise no question except as to the accuracy or sufficiency of the plans, specifications, or estimates, nor should they vary the plans or specifications, except upon the advice of the engineer or architect. Nothing was to prevent the engineer or architect, or the Works Committee, from taking action in cases of emergency; but such action would have to be reported to the Council forthwith. It was further proposed that the Works Committee should carry into execution all works which the Council resolves to execute without the intervention of a contractor, and should provide all necessary store-yards and workshops. The committee were to have power to contract, on behalf of the Council, for the supply of plant and material, provided that the amount of the contract did not exceed £500, and provided also that no contract involving an expenditure of more than £100 should be entered into except after public advertisement. They further recommended that the staff of the Works Committee should consist first of a "chief officer" at a salary of £1,000 per annum, whose duties shall include advising as to the purchase of stores, plant, and material, the regulation of all store-yards and workshops belonging to the Council, and the execution of all works carried out by the committee. The department is to be divided into three branches, those of

engineering, building, and stores. That the subordinate staff be as follows:—(a) General.—One first-class clerk, commencing at £200; one third-class clerk, commencing at £100. (b) In the engineering branch.—One engineer, salary £400; one cost clerk, salary £250; gangers, foremen, and labourers as necessity arises. (c) In the building branch.—One principal assistant for buildings, salary £250; pricing clerk, salary £200; measuring surveyor, salary £200; foremen and labourers as necessity arises. (d) In the store branch.—One principal storekeeper, salary £150; one third-class clerk, commencing at £100; store clerks at the various depots.

Mr. Fardell moved an amendment, deferring the consideration of the report till express powers had been granted by Parliament to the Council to establish a Works Department. The amendment, after discussion, was rejected by 82 to 28 votes. The recommendations of the committee were adopted with some modifications, including the fixing of the salary of the proposed chief officer at £700 instead of £1,000 per annum, and the alteration of his title to "manager of works and stores." The members to serve on this new department will be nominated at the L.C.C. meeting on Tuesday week, the 6th prox.

PLUMBERS' REGISTRATION AND EXAMINATIONS.

THE London Board of Examiners in connection with the National Registration of Plumbers met on Tuesday, at the Guildhall, London, Mr. Charles Hudson, Chairman of the Board of Examiners, presiding. The meeting was attended by the representatives of the several London Lodges of Operative Plumbers. Various matters with reference to the examination questions and practical tests for candidates for registration by the Plumbers' Company were discussed and adjusted. Regulations with reference to the conduct of such examinations were revised. Additional regulations for examinations in provincial centres were approved, the object being to facilitate those examinations. At the conclusion of the business the examiners dined with the wardens of the Company, the warden (Mr. W. H. Bishop) presiding. Sir Philip Magnus (renter warden) defined the functions of the examiners as being two-fold—to examine the work of the candidates for registration, and also to indicate by the character of their examination tests the lines on which should proceed the course of study, combined with practical work to be followed by plumbers, and the teaching which apprentice plumbers should receive. Mr. C. T. Millis, M.I.M.E., principal of the Educational department of the Borough-road Polytechnic Institute, stated that, although the attendance at the plumbers' classes at that institute had steadily increased, there had been no diminution in the attendance at the classes at any of the other London institutes, showing that the accommodation which had been provided at the Borough-road Institute had supplied an actual want. He also referred to the opening of a class for adult plumbers at the institute. Mr. J. R. Beeston (representing the West Central Lodge), Mr. C. Early (representing the Sydenham Lodge), and Mr. C. Dean (representing the No. 1 Lodge) of Operative Plumbers, and others, made reference to the increased interest taken in the technical education of plumbers and the registration system by the several lodges of operative plumbers in London. It was recommended that a mass meeting of London plumbers should be called to consider the present position of the registration movement and the extension of plumbers' classes in the London district. Mr. Geo. B. Davis (of the firm of George Jennings) mentioned several cases of plumbers in his firm taking employment under local sanitary authorities as sanitary inspectors.

The Lord Mayor of Dublin presided at the annual public meeting held the other day under the auspices of the Dublin District Council for the National Registration of Plumbers. There was a large and representative attendance. Dr. E. J. M'Weeney moved the following resolution:—"That the registration movement, which has now been fully organised throughout the United Kingdom, is worthy of support, because it is calculated to protect the public against the danger of bad plumbing." He said that this was a subject which came home to everyone's backdoor. The plumber's art was so intimately connected with the public health that its practice should never be intrusted to an inefficient hand, or an unin-

structed operative. That was why the registration movement, the object of which was to enforce the suitable education of plumbers, was a public necessity, and he might add, had successfully triumphed over its enemies. Sir Charles Cameron, medical officer of health for Dublin, seconded the resolution, and strongly supported the plumbers' registration movement. Mr. Simmons, Secretary Trades' Council, supported the resolution, which was adopted. On the motion of Mr. W. Kaye Parry, M.A., C.E., seconded by Mr. W. Walsh, secretary of the Dublin Lodge of Operative Plumbers, the following resolution was also carried unanimously:—"That the meeting is of opinion that the Plumbers' Registration Bill, introduced by the Worshipful Company of Plumbers during the last session of the Imperial Parliament, should be placed upon the statute book at the earliest opportunity, and the Irish Members of Parliament are hereby requested to give the Bill their active support, and that copies of this resolution be forwarded to the Right Hon. the Chief Secretary for Ireland and to the members for the City and County of Dublin."

BOOKS RECEIVED.

A Popular Handbook of Nonconformist Church Building, by JAMES CUBITT, F.R.I.B.A. (London: James Clarke and Co., Fleet-street), will be found a useful and suggestive little book to all engaged in the building of Nonconformist churches. Those of our readers who have read Mr. Cubitt's series of articles on this subject in our pages—of which the present little volume is practically a reprint, though it is not said so—will hardly need to be told of the views enunciated by the author, who has had some considerable experience in this branch of his profession. Mr. Cubitt distinguishes two tendencies, both of which have a claim on the Nonconformist church builder. One is the "congregational," and the other the "ecclesiastical" tendency. The first of these regards that the building shall be primarily adapted for preaching, that every member shall see and hear the preacher easily, and be in actual contact with him. The prayers, too, are extemporaneous, and must be distinctly heard, as there is no liturgy which everyone can follow, whether he hears or not. The singing also is congregational, not choral, and, therefore, the choir must be in the congregation or auditorium. The "ecclesiastical" ideal is not so concerned with simply practical requirements: they look for, as the author says, "a high standard in the accessories of public worship—in architecture and music and the arts." Beauty, as well as truth, is aimed at, and the ecclesiastical builder likes the church to have some traditional form and association with those of former ages. Mr. Cubitt clearly sees the advantage of reconciling these two tendencies, and his little book of suggestions and instructions, accompanied, as they are, by plans of churches of different types, will be read with profit by architects and others. He names L, T, and cruciform plans as three varieties of columnless buildings suitable for the object of preaching and for congregational requirements. But he also points out how columns may be employed with architectural effect, and help to break up echoes, and some of the best plans show columns kept clear of the central space, but limited to a few. Many plans of the "central area" type, based on the square, and on octagons and other polygons, are illustrated and described. — *Electric Light, its Production and Use*, by JOHN W. URQUHART, Electrician, with numerous illustrations, fifth edition revised (London: Crosby Lockwood and Son) is a new edition of a treatise we lately noticed. The revision and additions have made Mr. Urquhart's book still more complete as a manual. The chapter on the "Control of Central Station Lighting" will be of value and interest to all students and engineers. The illustrations are clear and well drawn, not always the case in these handbooks. Every necessary information is given on the various appliances and new developments of electric machines, accumulators, and lamps, and, as an elementary manual on the subject, we know of no better book.—A fifth edition, enlarged and revised, is to hand of the well-known and reliable *Handbook of House Property*, by E. L. TARBURCK (London: Crosby Lockwood and Son.) The book now consists of four divisions, the first three dealing with the Law, Valuation, and Building of Houses, and the last with the

Art of House Building.—*Woodwork* (The English Sloyd), by S. BARTER, instructor of manual training in woodwork to the London School Board, &c., with illustrations (London: Whittaker and Co.). Mr. Barter's octavo volume is admirably printed, and illustrated by diagrams of work and views of manual operations, adding much to the value and usefulness of the work as a guide for public elementary schools. In the preface, which is written by Mr. George Ricks, B.Sc.Lond., it is clearly laid down that "manual training is a special training of the senses of sight, touch, and muscular perception by means of various occupations; and it is the training of these faculties, not so much for their own sake as it is for the training of the mind." The main aim is educational; the essence of manual training lies in the *practice*, not in the *production*. Upon these grounds Mr. Barter's work is composed. The chapter on drawing and projection is useful and well illustrated by diagrams; the next chapter treats on timber, its growth, seasoning by water and hot-air, shrinkage, and the various kinds of conifers and broad-leaved woods. The chapters on tools and benchwork occupy a large portion of the volume, and various exercises are well explained and illustrated by examples of marking, sawing, and chiselling, planing, jointing of different kinds of framing. A useful chapter on the workroom and its fitting concludes this useful work. The models include newspaper racks, picture-frames, boxes, brackets, letter-cases, and a number of useful objects, describing the materials and operations. As a manual of instruction on woodwork, Mr. S. Barter's book will be found an admirable guide, as each exercise is accompanied by the necessary drawings and instructions, leading the pupil from an intelligent conception of the subject through the operations needed to construct the required object. As a training of manual and visual faculties of the student, nothing better can be given.—*Treatise on Thermodynamics*, by PETER ALEXANDER, M.A., Ex-Breadalbane Scholar, Glasgow University (London: Longmans, Green, and Co.), is a work in which the subject is treated in all its details from the two laws, one enunciated by Joule and Rankine, that "Heat and mechanical energy are mutually convertible"; the second by Thomson, that "If an engine be such that when it is worked backwards, the physical and mechanical energies in every part of its motion are all reversed, it produces as much mechanical effect as can be produced by any thermodynamic engine with the same temperature of source and refrigeration from a given quantity of heat." Upon these laws Thomson and Joule have established the science of thermodynamics. Mr. Alexander's treatise gives a succinct mathematical exposition of these laws; but the pages are too full of algebraic expressions and formulæ to be understood by the general student, or to permit of examination in these pages.—*Lockwood's Dictionary of Mechanical Engineering Terms*, edited by A. FOREMAN PATTERN-MAKER; second edition revised (London: Crosby Lockwood and Son), is well known as one of the best dictionaries of the kind; and this edition, which has been revised and considerably extended by additions in the form of an appendix, needs little commendation from us. The editor, as a foreman pattern-maker engaged in factory duties all his life, has had undoubted opportunities for the compilation of such a dictionary, which will be of great use to all engineering pupils and amateurs. The terms are brief and concisely stated, and show a practical knowledge of the subjects.

BRIDGE OVER THE OHIO.

THE cantilever highway bridge at Cincinnati across the Ohio River, between Cincinnati and Newport, is a structure of some magnitude, designed by Mr. A. H. Porter, approved by Ferris, Kaufman and Co. The roadway is 24ft. wide, with side-walks of 7ft. each, and the total length is 2,966ft., with a cantilever span of 520ft. between centres of piers. There are six main spans, twenty-eight pedestals, and nine piers; all these piers are of masonry. Full details and description of this bridge is given in the *Transactions of the American Society of Civil Engineers*, by Messrs. Gustave Kaufman and L. C. Osborn, members. The cantilever span is minutely detailed, and a strain sheet given. The live load for all truss members receiving more than one panel load is 80lb. per square foot for suspended span and cantilever arms. For

stringers, floor-beams, and long suspenders, 100lb. per square foot of clear roadway and side walks. In the calculation, the following condition of live-load are assumed: For main truss members the roadway and walks will be considered loaded; for long suspenders, roadway and one side walk only will be considered loaded. Wind stresses are calculated for a pressure of 30lb. per square foot on the exposed surface of both trusses and railings.

OBITUARY.

MR. WILLIAM SIMPSON, builder, of Alyth, near Dundee, died on Thursday last week. Mr. Simpson, on account of advancing years, had been in frail health for some time. He went to Alyth during the erection of the parish church in the years 1837-8-9, at which large job he was employed as a foreman. After this he contracted on his own account, and built many large houses in the town and district. Mr. Simpson was predeceased by his wife, and is survived by two sons and three daughters, the eldest of the former being the Rev. William Simpson, of Bonhill. Deceased was in the 85th year of his age.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

DUNDEE INSTITUTE OF ARCHITECTURE, SCIENCE, AND ART.—The eighth annual report just published congratulates the members on the fact that the Institute continues to grow in numbers and influence. Twenty-four ladies have been admitted to the Associateship of the Institute, in accordance with amendments in the constitution agreed to at the last annual meeting. Last year's roll contained the names of 50 members, which is increased this year to 54 by the transfer of one from associate to member, and the election of five new members, while two have resigned. In the former session the associates numbered 167. This year, by the death of two, transfer of one, resignation of 10, and election of 35 (24 ladies and 11 gentlemen), the number is increased to 189. The roll of honorary members remains as before. The treasurer's balance-sheet shows an increased income, but along with that a very largely increased expenditure, caused principally by the greater number of lectures and a considerable deficit on the two excursions.

GLASGOW INSTITUTE OF ARCHITECTS.—A general meeting of this institute was held in Glasgow on Friday, Mr. W. F. Salmon, president, in the chair. The chairman stated that the meeting had been called to consider a unanimous recommendation by the council with reference to the Lanarkshire County Council competitions. As the conditions of competitions for the above were unsatisfactory in the following points, the Institute recommended that members should take no part in them: (1) As the competitors are not assured that an architect of experience will be associated with the medical officer to advise the committee in its decision; (2) that no guarantee is given that the author of the design placed first in the order of merit will be employed to carry out the work (provided that inquiries as to his status prove satisfactory); and (3) that the terms of employment of the architect selected to carry out the work are not stated. The chairman commented on the unsatisfactory nature of the conditions of competition, and reference was made to the memorial, which had been largely signed by the profession throughout the country, by which they pledged themselves not to take part in any competition unless there was a professional assessor appointed. On the motion of Mr. Campbell Douglas, seconded by Mr. John Honeyman, the recommendation was unanimously adopted.

LEEDS AND YORKSHIRE ARCHITECTURAL SOCIETY.—The opening address of the 17th session of this society was delivered in the Law Institute, Leeds, on Monday night, by the President, Mr. G. B. Bulmer, F.R.I.B.A. Since the formation of that society the air had, the President said, been rife from time to time with the sound of their discontent because not one good architect could be found in Leeds; but "they had changed all that now," and it was they who had helped to throw oil on the troubled waters. At the present moment there were several public works in this town just finished or being erected from the designs of Leeds men, and he felt sure that a quiet undercurrent of thought existing amongst

them had largely helped to forward this result, and where recourse had been had to competition, fairer and more honourable conditions than had usually obtained in the past had been secured for them by their sympathy. Having referred with satisfaction to the increase in the muster-roll from 74 in 1882 to 110 in the present year, Mr. Bulmer mentioned an idea which had occurred to him—the amalgamation of the Leeds, York, and Bradford societies, as representing the united county. Sheffield was so far on the border that it might perhaps be taken as the centre of a large district lying to the south of it. A gentleman had recently asked him: "Do you think your society has done any good? An unqualified affirmative could be the only answer. Those who had regularly attended their lectures, numbering about 120 up to date, on a variety of subjects connected with their profession, must have been benefited thereby. The Associates and pupils who earned their prizes and enjoyed the educational assistance they afforded, must see its uses when they reflected that 17 years ago there were no prizes, no library, and no encouragement or assistance from their senior members. No reflective mind could fail to see that they had constructed a powerful machine. It remained for them to use it to the best advantage, and so give additional evidence that they had not worked in vain. Mr. W. Watson, Wakefield, proposed, and Mr. J. Holmes Greaves seconded, a vote of thanks to the President. A set of drawings of Skelton Church were exhibited by Mr. J. L. Grant, who has entered these for the society's silver medal and the prize of five guineas given by the President. A number of sketches by Mr. T. D. Brooks, executed by him in connection with the travelling studentship of ten guineas awarded by the society, were also exhibited. The syllabus for the session thus inaugurated is as follows: Dec. 4, "Vaulting," by A. Keen; Dec. 19, Social Evening; Jan. 23, 1893, "Electric Lighting," by T. S. Watney; Feb. 6, "The Knights Templars in England," by J. W. Moor Kill; Feb. 20, "Remarks on Colour Decoration," by H. V. Lanchester; March 6, Exhibition of Architectural Drawings, shown by limelight; March 20, "Dore Cistercian Abbey Herefordshire," by Roland W. Paul; April 24, Annual Report and Election of Officers.

LIVERPOOL ARCHITECTURAL SOCIETY.—A special meeting of this society took place at the society's library, Liverpool, when a paper was read by Mr. Wm. Owen, F.R.I.B.A., of Warrington, on "Chester Cathedral." The paper treated of the history of this interesting structure in a most exhaustive manner—bringing it from its earliest inception to the present time, and a well-deserved tribute to the late Sir Geo. Gilbert Scott, the restorer of the fabric, was paid by the lecturer. The paper was well supported by large and well-executed drawings and sketches, illustrating the four periods of Gothic architecture, which are so well exemplified in this charming monument of Mediæval art. A ground plan of the building, coloured as to show distinctly the portions of the building which were built in the Norman, Early Decorated, and Perpendicular periods, with a corresponding chart showing the dates and reigns during which these styles prevailed, was a unique and edifying illustration of the lecturer's remarks, which were listened to by a large gathering of students and older members with much appreciation.

CHIPS.

The parish church of Shrawardine, Salop, has been reopened after restoration. The church stands on the site of a Norman edifice destroyed in the Civil War, the nave of the present building dating from 1649, and the chancel from 1722. The alterations include new seats made out of the oak pews, stalls for the choir, a chancel screen with doors, a chancel arch, and paving the floor with tiles. The work was carried out by Mr. R. Price, contractor, of Coleham, Shrewsbury, from plans by Mr. Percy H. Currey, architect, of Derby.

At the last meeting of the Brighton town council, a proposal was brought forward for the erection of a winter garden, at the cost of about £25,000, on the western lawn of the pavilion. After discussion a resolution was carried affirming the desirability of a winter garden, and referring the whole matter to a special committee to consider and report at an early date.

Mr. James Hicks, architect, Redruth, has been instructed to prepare plans and a scheme for providing a hall over the Butchers' Market at Redruth.

ILLUSTRATIONS.

HYDE PARK COURT.—WIGHTWICK MANOR.—DRYBURGH ABBEY.—ELMLEY CASTLE CHURCH.—A STUDIO.—THIRTEENTH-CENTURY SOUTH ITALIAN CARVED WOODEN COLUMNS TO ORGAN.—PUBLIC SCHOOL FOR GIRLS, HONGKONG.

Our Illustrations.

HYDE PARK COURT.

THIS colossal block of mansions has not before been illustrated, although considerable attention has been attracted to the work, owing to the legal proceedings which were taken by the County Council to prevent the erection being carried up to an excessive height. Hyde Park Court is situated in the main thoroughfare of Knightsbridge, overlooking in the rear Rotten Row, with the Park and Serpentine beyond. The building is fitted with every modern improvement. It is built of red brick, with stone dressings and ornamentation; and the numerous balconies and balustrades of stone and iron, the double ascent of bays, the portico, supported on massive columns, and the turret at the extreme top, combine to give it an appearance of grace and solidity. Everything in connection with the building has been done upon a vast scale. The culinary department in the basement is fitted throughout on the latest and most approved principles. The sculleries, vegetable, pastry, and other rooms are all distinct from the kitchen; and gas is used as little as possible in the cooking operations. The culinary apparatus has been erected at a cost of over £3,000, and, with the electric light, the tiled floors and walls, and the well-ventilated, airy apartments, cleanliness is attained. On the lower ground floor—which is on a level with, and looks upon, Knightsbridge-road—are three billiard rooms for the use of the tenants, the walls of which are of carved pine panelling. Then there are card and smoking rooms, a succession of lavatories, and a hair-dressing saloon. The entrance-hall is approached from the porticoed entrance in Knightsbridge, through carved walnut swing-doors. A centre flight of white marble steps leads up to the ground floor level, these, and the passage on either side, being flanked by a marble balustrade. The floor, the walls relieved by pilasters, with gilded capitals, the columns, the massive mantel and fireplace, with clock over, are all of marble, in variety of colour and working. The panellled ceiling is a fine specimen of frescoed work. To the left of this hall are the manager's and general offices, service-room, and ladies' cloak-room, and beyond these the general reception and reading-room. The breakfast and dining-room, overlooking the Row and the Park, is decorated in much the same style; both fittings and furniture being all in character. The first, second, and third floors are arranged as family suites, self-contained, each consisting of hall, drawing and dining rooms, four bedrooms, bath-room (with fireplace), kitchen, and excellently-appointed offices, the inner corridor being of oak wood-block flooring. These are decorated, fitted, and furnished to suit incoming tenants. Where a family does not care to be troubled with a large staff of servants and

culinary matters—board *en pension* can be obtained downstairs—the kitchen and offices are converted into additional bedrooms. There are four family and one bachelor's suite on each of these floors. In the rear of the building is the most striking feature of all, by means of which perfect immunity from danger in case of fire is afforded. This is a large iron spiral staircase, at some distance from the building, but communicating with every floor. The whole erection—walls, floors, partitions, and staircases—is of fireproof construction, thereby reducing the chances of a fire to a minimum; but here, with this spiral staircase, if one should occur, the egress of the inmates is easy, sure, and safe. As a further safeguard two fire hydrants are affixed on every floor. This spiral staircase takes its rise from a stone loggia, which, immediately overlooking the Row and Park, and communicating with a balcony, forms a pleasant summer's evening lounge and promenade. A comfortable hydraulic elevator, to take ten persons, gives access to all floors. This elevator is available for use night and day. The building has been completed from the designs of the architect, Mr. Thomas Archer, of Sackville-street, Piccadilly. Messrs. J. W. Hobbs and Co. were the builders.

ADDITION TO WIGHTWICK MANOR.

It is only about four years since Messrs. Grayson and Ould built this house in the old timber style for Mr. S. Theo. Mander in the country near Wolverhampton, but they have now been employed to build an addition to it, which is as large as the entire house originally built. This consists of a hall or "great parlour," about 50ft. by 24ft. with an open panellled roof and minstrels' gallery, a billiard-room, dining-room, secondary staircase, and servants' offices, with bedrooms over all but the parlour. The style adopted is again the black and white, but it is more massive, as well as more ornate, than the original structure. The chimneys are twisted, of South Country brick, from Mr. James Brown, of London. Messrs. Rattee and Kett, of Cambridge, supplied the oak work, and the contractor is Mr. Henry Wilcock, of Wolverhampton. Illustrations of the original house will be found in the BUILDING NEWS for July 12, 1889.

DRYBURGH ABBEY.

THE architecture of Dryburgh Abbey is for the most part Norman, but much belongs to a far earlier date. Among the ruins may be observed four distinct styles of arches, viz.: The massive Roman arch, with its square sides; the deeply splayed Saxon; the pillared and intersected Norman; and the Early English Gothic. The chapter-house and abbot's parlour are of much greater antiquity than the church, which was probably never wholly repaired after its destruction in 1322. The church was in the form of a cross, with aisles. The nave was 190ft. long, by 75ft. broad. Under the high altar, James Stuart (of the Darnley family), the last abbot, is buried. The illustration is of part of the north transept, called St. Mary's Aisle, and is of beautiful Early English Gothic work. It is in this aisle that Sir Walter Scott, Bart., is buried; also Lady Scott; and his son-in-law and biographer, J. G. Lockhart. Little now remains of the monastery but the chapter-house, St. Modan's Chapel, and between them a large vaulted chamber, now the family vault of the Biber Erskines. The chapter-house is 47ft. long by 23ft. broad, 20ft. high. Beneath the floor of the chapter-house lie the mortal remains of the founders, Hugo de Morville and Beatrix Beauchamp, his wife. The abbey was founded in the year 1150. The illustration of Dryburgh Abbey and Elmley Castle Church, Worcestershire, are from photographs taken by Mr. Lionel Erskine Westropp.

THE CHURCH OF ST. MARY, ELMLEY CASTLE, WORCESTERSHIRE.

THE Church of Elmley is of Saxon origin; the remains of the Early walls are to be seen (the stones standing edgewise) in the chancel, built either by the Saxon tenants of the Bishop of Worcester before the Conquest, or by the Normans very soon afterwards. The church was restored at the time of the Reformation. In the south aisle the pillars below the transept are much plainer than the others, looking very much as if they had been cut out of the old wall when the aisle was added on, they are square and have no capitals. In the south transept there is a recess in the wall, which looks as if it

had belonged to a side altar, the place at which probably the special worship of the Virgin Mary was carried on. The upper part of the tower was probably built about this time (1546). The pedestal of the font is a subject of interest: the lower part is decidedly Norman of very Early date; the bowl is of more recent date, probably time of the Tudors. The church was beautifully restored about 14 years ago.

STUDIO FOR MR. DENDY SADLER.

WE illustrate this week the interior of a studio which is shortly to be erected at Hampstead for Mr. W. Dendy Sadler, the well-known artist, from the drawings and under the superintendence of Mr. Fred J. Lewis, architect and sanitary surveyor, of Clement's Inn Chambers, 263, Strand. Our sketch shows one end of the studio, across which runs an oak balcony, supported upon two elaborately carved pillars. The balcony front is richly carved in a floriated design, and was secured, besmeared with paint, on the demolition of one of the City churches. The accommodation for the models is provided beneath the floor of the studio, and is reached by a flight of stairs beneath the balcony, thus securing the models the greatest amount of comfort, with the least expenditure of floor space. The ceiling is divided into two portions by a bold oak beam, or rather casing to a steel girder, which carries the rooms over the ceiling above; one half is deeply coved, so as to allow sufficient head room for persons standing upon the balcony, whilst the remainder of the ceiling is flat, with oak moulded ribs, thus dividing the ceiling into squares. The walls beneath the higher position of the room are covered with oak panelling and Italian leathers, from the floor level up to the frieze, which is plain white, whilst the other portion of the room is provided with a dado, above which tapestry will be hung. The glass-house, which is to be used for painting exterior views, is 25ft. square, and will lead directly out of the studio.

CARVED WOODEN COLUMNS FROM SOUTH ITALY.

MR. WYKE BAYLISS, at the opening meeting of the Society of Architects, as reported in last week's BUILDING NEWS, said: "There was one of the loveliest things in the world that we Englishmen could cultivate, and that was the art of wood-carving"—words that were received with applause. The examples of Italian wood-carving, sketched at the South Kensington Museum, which we illustrate in our present issue, show what that country could produce as early as the thirteenth century. Crude as they possibly are in workmanship, they are full of life and feeling, and afford by contrast an instance of the deterioration of spirit which modern work displays only too often. Of technical skill there is abundance—of living ideas nearly nothing. One can imagine the ancient workman-artist chipping out the ideas as they formed in his mind, and revealing his varying moods—here putting a little humour in his work, there piety, here expressing grace and delicacy, there revelling in an uncouth form or quaint device, and so producing, whatever its faults may be, something which has human interest in it. On the contrary, most of our modern work, turned out with the placidity and monotony of a machine, means, and consequently suggests, nothing; and, even if the eye is satisfied, the mind is not regaled.

PUBLIC SCHOOL FOR GIRLS, HONGKONG.

THIS building is now being erected in the Hollywood-road, Victoria, Hongkong. It is designed to cost, with furniture and fittings, 30,000 dolars; and it is the intention of the Hon. E. R. Bellios, who has taken a great interest in educational movements, and at whose expense the building is being erected, to hand it over upon its completion to the Colonial Government for the promotion of education among the Chinese and Eurasian population. The school building is a three-storied one, with four class-rooms upon each floor, and is arranged to accommodate in the first case 576 scholars. The principal entrance is upon the Hollywood-road, from which access is obtained directly to the first-floor level. The walls are of Canton red and blue bricks plastered, with white granite plinth, dressings, &c. The roofs are to be covered with a double course of Canton pan and roll tiles. The floors are to be of teak, and most of the carpentry is of hardwood. Mr. Edward A. Ram, of Messrs. Sharp and Co., Hongkong, is the architect, and the work is being executed by Mr. Lai Yow, contractor, of Hongkong.

PUBLIC SCHOOL FOR GIRLS HONG-KONG.

EDWARD A. RAM, ARCHT.
HONG-KONG.

WAYSIDE NOTES.

THE long-expected competition for the new "Blue Coat School" is announced, and a very good thing it will be—for those who may be invited to compete. By general consent, this is a competition for the princes only of the architectural art or profession—there are not many of them left, nowadays. The ordinary practitioner can only look on, deriving, perchance, something of that satisfaction felt by a hungry urchin flattening his nose against a baker's window-pane—if my simile be excused. I have watched with much interest for the appearance of this competition ever since it was announced that the Council of Almoners of Christ's Hospital had secured a site for their proposed new building near Horsham. That it must prove a competitor of the day, if not epoch-making, at least more than a nine-days' wonder, was a foregone conclusion; but we hardly anticipated an array of seven judges or assessors, of varied shades of opinion, and, doubtless, very diverse tastes—possibly capabilities.

One fears that the voice of the one architectural assessor may be somewhat lost in the six-sevenths of non-professional opinion that will be given. I fancy that a proportion of two-sevenths of architectural elements would have been more to the interest of the Almoners, and that had the assistance of Mr. Henry Currey been secured in addition to those able gentlemen appointed, the Council would have had cause for self-congratulation.

We need by no means be averse to laymen as judges, providing that they form the rank-and-file of the adjudicating board, and are well and sufficiently officered, so to speak, by experienced architectural assessors. If the lay element is to swamp the professional, however, evil must follow.

The £100 allowance to each competitor is very liberal, and *should* be so when we consider the labour involved in the work of preparing the plans. The competition advertisement gives some idea of the extent of ground the new "hospital" will cover. As to style, I rather fancy that Tudor will be the thing—Free or *fin-de-siècle* Tudor, let us call it.

There is really a rush of competition work. Already several are in hand; last week we noticed the St. Pancras competition, and now here is a budget comprised of the new Blue Coat School, a County Council hall in Yorkshire, and new baths and wash-houses for Chelsea. The one hailing from West Riding is in itself an important affair, with premiums of £200, £100, and £50. I see that no assessor is mentioned in connection with the new baths for Chelsea. In view of recent happenings, we should like to see such an individual definitely appointed.

Mr. Waterhouse, I read, has been declaring against the chronic plague of advertisement posters. And quite as good an art critic defends such "ads," and pronounces them to be a "cheerful," if common, objects in the Queen's highway and other places.

The Panama Canal scheme has proved a veritable bubble. Probably had not the redoubtable M. de Lesseps been connected with the venture the bubble would have burst years ago. Many will call to mind the tenour of the occasional reports on the progress of the works that appeared in the daily Press. Tales of rotting machinery, blunders, futile endeavours, and other things scarcely encouraging to shareholders have been plentiful. For M. de Lesseps one is sorry, though we know that, come what may, the Suez Canal will certainly tide him over any difficulty connected with the Panama Canal; but the affair as a whole shows that "the triumph of mind over matter," of which we hear so much nowadays, is not so complete that mankind can become boastful.

Large derricks on high stagings are really very picturesque things. There are two beauties in a new job somewhere over against the St. James's Hall. One I note as possessing a decided flavour of the weird, with its mammoth boiler-chimney and open fire-door glowing in the winter twilight through driving clouds of steam.

The new pier works at Brighton do not progress

with remarkable rapidity. Their condition this week seemed to me little in advance of a month ago. These certainly are not good-working days, particularly for sea work; otherwise the building of light piers should not be a very lengthy operation.

I heartily sympathise with your correspondent, Mr. Herbert Wade, and with all other architects similarly situated. There appears to be only one method of procedure. Hold yourself aloof, and let the public see that you are independent of both them and the rabble who trade as architects. It may mean trial and struggle, but the time will surely come when people will recognise the architect, and know him from the charlatan and impostor. I speak with full personal experience of such positions as that of your correspondent.

I hear that the old Market Hall at Tonbridge is encompassed by several desirous of its destruction on the plea of making more room in the High-street. The picturesque old building was recently illustrated in the *Graphic* by an admirable pen-and-ink drawing by Mr. W. B. Boulton. With the adjoining famous "Chequers" Inn, the hall makes a fine picture, and Mr. Boulton has selected the most effective point of sight. There is a scheme at Tonbridge for pulling down much of the old High-street, and rebuilding the street with an increased width. It is not easy, however, to see where the old Market Hall offends, any block on market-days being in the narrow roadway rearer the railway station.

Great improvements are promised at Dover. The next session of Parliament will see several applications for works at this seaport. The most extensive scheme is the construction of a marine drive and promenade between Dover and St. Margaret's Bay, a distance of three or four miles. This is a private enterprise, and is estimated to cost little less than £200,000. The formation of a sea-wall and building sites is contemplated. The Corporation of Dover have decided to proceed with their street improvement scheme inaugurated last year, and will apply for further powers to enable them to make a new thoroughfare and widen one of the main arteries of the town, an outlay of £50,000 or £60,000 being contemplated. Besides these projected works, a contract for £115,000 has just been entered into for the first portion of the new harbour, which will cost at least another quarter of a million to complete. The South-Eastern Railway Company, too, are to be abreast of the times—at Dover, if not elsewhere—and have obtained the necessary powers for acquiring extensive property at the west end of the town for the erection of a new terminus.

A limited company that during its seven years existence has paid no less than 85½ per cent. on the total share capital, and whose profits it is anticipated will, during the coming year, balance the whole subscribed capital, is a noteworthy and comfortable exception in these dreary days of declining business and lamentable liquidations. If Mr. Robert Boyle's exhaustless energy and perennial good luck remain with his company, the happy shareholders of Robert Boyle and Son, Limited, who, I see, met to congratulate each other at the City Terminus Hotel on the 16th inst., may fairly hope, one of these days, to see their holdings become as valuable as New River Shares. Some of the contracts carried out by the company are colossal ones, and the profits are, no doubt, handsome; but one of the best signs in connection with the concern is that, while able to divide these handsome returns, no opportunity is lost of adding year by year substantial amounts to a reserve fund, which, as it stands at present, is a solid guarantee against the evils associated with the sanguine improvidence that eats all its cake as soon as it is earned.

The special tribunal set up under the County Council Act of 1890 to settle line of frontage cases, has already had several cases before it. The tribunal as at present constituted—viz., Mr. Arthur Cates (Vice-President Royal Institute of British Architects), Mr. F. C. Shoppee (President Surveyors' Institution), and Dr. Longstaff (London County Council), heard an appeal last week in respect of the line of frontage to a large corner plot of building ground at Camberwell. The superintending architect of the County Council (Mr. T. Blashill, F.R.I.B.A., F.S.I.)

and Mr. Reynolds, surveyor to the Camberwell vestry, being present, and Mr. P. E. Pilditch, of Messrs. Chadwicks, architects and surveyors, representing the appellant and Mr. W. D. Belcher an adjoining owner. The decision was reserved, but it was forthcoming within a very few days—indeed, the despatch with which the decisions of the tribunal have been given has been a source of considerable satisfaction to those surveyors who, on their clients' behalf, have had to appear before it. The profession generally, being aware of the great demand upon the time of these lay judges, speaks in the highest terms of the public spirit which prompts them to spend so many valuable hours of their time in entirely unpaid labour. GOTH.

CHIPS.

The memorial hospital and institute at Almondsbury was opened by the Duchess of Rutland on the 16th inst. The building is L-shaped on plan, modernised Queen Anne in style, and built of local bricks with freestone dressings. Mr. C. E. Ponting, of Marlborough, is the architect, and Mr. Perkins the builder.

Receiving orders have been granted in the cases of Joseph Clever, of 54, New Broad-street, E.C. and 7, Richmond-terrace, The Level, Brighton, architect; and of Frederick Billings, St. Mary Cray, architect.

Two blocks of schools are about to be erected in Bournemouth for a school committee. For that in Malmesbury Park district the tender of Messrs. George and Harding, of Bournemouth, has been accepted at £1,911; and for that in Gladstone-road, Boscombe, the tender of Mr. W. Hoare, of the same town, has been taken at £1,535.

The foundation-stone of new schools in connection with the Roman Catholics, at Shelfield, were laid last week. The building is from the designs of Mr. S. Loxton, and is being erected by Mr. Bantock, Walsall. The cost is £530.

The Clason Memorial Free Church, which has been erected in the south district of Motherwell at a cost of £2,000, was opened on Friday. The church is in Gothic style, and is seated for 600 persons.

Dr. Giulio Salviati and Mr. Arthur Crofts Powell have been presented by the Glass Sellers' Company with the freedom "as a mark of acknowledgment and high appreciation of their successful efforts to improve and develop the manufacture of artistic glass wares."

At Carpenters' Hall, on Friday, Sir Douglas Galton, K.C.B., D.C.L., gave a lecture on "Ventilation, Warming, and Lighting of Private and Public Buildings." Sir Douglas Galton commenced by asking, What was pure air? and proceeded to answer the question. In every condition there was dust in the air—of course, much more in towns than in the country; still, even on the mountain top there was dust. If there were no dust there would be no fog. The amount of impure air "permissible" in a room was referred to, and the lecturer went on to show that every care should be taken to get the air as pure as possible.

George Price Dicken, farmer, of Ruabon, was committed for trial at Wrexham on Friday, on a charge of publishing a defamatory libel on a postcard, concerning Mr. Henry Jenks, manager and director of the Ruabon Brick and Terracotta Company. The writer of the card described the prosecutor as a company floater and felon, and said he had been one of his thieves. The prisoner had admitted writing the postcard, and declared it was the truth.

The Old Meeting House, Norwich, now used as a Congregational church, has been reopened, after extensive alterations. The building has been entirely re-seated, the old oak having been re-used as far as practicable. New floors have been laid to gallery and ground floor, and the aisles have been paved with wood blocks. The contractor for the work was Mr. G. E. Hawes, and the architect Mr. J. Pender West, of the firm of Pearce and West, Lowestoft.

Mr. T. F. Tickner was the architect to the proposed new schools in Brickkiln-lane, for the school board for Foleshill, near Coventry, the contract for which was cancelled by the present board. Mr. Tickner sent a claim for compensation and for work done, and after some months' delay the school board examined his claim. The clerk gave the result of the scrutiny, stating that the chairman and himself, who were deputed by the board to inquire into the matter, had decided to disallow several items, such as claims for attendance, and they had come to the conclusion that Mr. Tickner was legally entitled to a sum of £73 9s. Mr. Tickner had consented to receive this sum in settlement of all claims, but he would not bind himself to the engagement unless a cheque was drawn that night. After some demur a cheque was drawn for the amount.

COMPETITIONS.

BRIXTON.—The Baths Commissioners of Lambeth have purchased the Polytechnic Institution in Ferndale-road, Brixton, for £8,000, for re-conversion into public baths, for which the premises were originally erected. The commissioners instructed three architects to prepare designs for a complete set of baths and wash-houses, preserving the existing swimming bath as a cheap second-class bath, and adding a first-class swimming bath for men, an extra swimming bath for women, private separate baths for both men and women, a Turkish bath, and accommodation for ten washers, with space for increasing the number of washers. The three architects—Messrs. Aldwinckle, Bell, and Tiltman—all sent in designs, which were referred to Mr. Henry Currey for his opinion as assessor, and he placed the competitors in the following order—viz., first, Mr. A. Hessel Tiltman; second, Mr. T. W. Aldwinckle; third, Mr. C. Bell. The purchase for the site being added to Mr. Tiltman's estimate of £14,500 for alterations will give a total of £22,500, and if to this is added the architect's commission of 5 per cent., and the expenses of the purchase and other incidental charges, the gross amount will still not exceed £25,000, and if to this sum is added £5,000 to allow for alterations and possible improvements to the design, and as a margin for the builder's tenders exceeding Mr. Tiltman's estimate, the amount altogether will not exceed £30,000 in all. The vestry have approved the agreement, and have given permission to the commissioners to borrow the sum of £8,000 to defray the purchase money.

THE BURNS STATUE FOR CHICAGO.—Mr. W. G. Stevenson, A.R.S.A., Edinburgh, has been informed by Mr. W. Gardiner, the treasurer of the Chicago Burns Monument Association, that his model of the poet has been selected from the thirty designs sent in for competition. The committee have about £3,000 in hand to expend upon the monument, and the sculptor has undertaken to execute a statue in bronze 11ft. high, with a granite pedestal about 12ft. high displaying bas-reliefs illustrative of scenes in the poet's works. The design represents the bard standing, his right hand holding a pencil and grasping the lapel of his coat, while in his left rests a note-book on the corresponding limb. Both the head and the costume will be modelled from the Nasmyth portraits.

KILLARNEY.—A PRINCIPLE PREMIUM.—The town commissioners of Killarney received at their last meeting a report from a committee as to the proposed Town Hall. They recommended that a site in Ballyvalley-lane be leased for 300 years at an annual rent of £300, and that upon this plot they should erect a building of one story, having in front two rooms suitable as commissioners' private offices and as committee rooms; in the centre one large hall, 94ft. long by 33ft. wide, and at the back two retiring-rooms, fitted with w.c.'s and lavatories. The committee added: "A prize of, say, £1 [!] to be offered by public advertisement for a plan, specification, and estimate, the rejected plans, &c., to be returned, and those accepted to become the property of the commissioners." It is a pity the committee could not be persuaded to raise the premium to a guinea, as such a sum would have looked more professional. We regret to add that, although the report stated that the ratepayers were unanimously in favour of the scheme, it hangs fire, its consideration having been adjourned as some of the commissioners were not satisfied that the best site had been selected.

WALSALL PUBLIC BATHS.—The General Purposes Committee have passed a resolution recommending that the plan of Mr. H. T. Bonner for the public baths be carried out, subject to the detailed specifications being approved by the committee, and to its being found, on tenders being obtained, that the work can be carried out by approved contractors at a total cost not exceeding £7,700.

A new parish church is to be erected at Troon from plans by Mr. H. J. Blanc, A.R.S.A., architect, Edinburgh. The present edifice dates from the end of the last century.

The sum of £6,000 asked for by the Dean and Chapter of Gloucester Cathedral to enable them to put the exterior of the building in a proper state of repair, has been raised, and the work is in active progress, under the direction of Mr. F. Waller, the cathedral architect.

Building Intelligence.

BRISTOL.—Further building developments at the University College are in progress in the erection of an engineering wing, to which the city council have contributed £2,000. It is expected to be finished early next spring. On the ground floor are to be a workshop and casting-shop, with a large boiler-house attached. On the two floors above are lecture-rooms, drawing, and class-rooms. The engineering wing will form one side of the future great quadrangle which is included in the complete design of the college buildings. Mr. F. Bligh Bond is the architect, and Mr. W. Church, Wapping, Bristol, the contractor. A medical wing is also in course of erection at the college from Mr. Bond's designs, Mr. G. Humphreys, of Stapleton-road, Bristol, being the contractor.

LINCOLN.—The foundation-stone of the new R.C. Church of St. Hugh was laid on Friday. The church will face Monks-road, and the style is Early English. The walls are of brick, faced externally with Greetwell stone, and covered internally with plaster, for the purpose of future coloured decoration. The dressings are of Douling stone. The columns on exterior, and to the nave arcade, are to be of red Corsehill stone, the latter having Portland stone bases. The church will seat about 500, and consists of a nave 87ft. by 35ft., with clerestory, processional aisle, and chapel on each side. There are also a sanctuary, 30ft. by 30ft., organ chamber, 21ft. by 20ft., and two sacristies and baptistery. The tower and spire will rise to a height of 140ft. above the ground. The contract has been taken by Messrs. H. S. and W. Close, contractors, of Lincoln, and will be executed from the designs and under the superintendence of Mr. Albert Vickers, 151, Strand, W.C.

LINTHORPE, MIDDLESBROUGH.—On Saturday the Archbishop of York consecrated the Church of St. Barnabas, at Linthorpe, Middlesbrough. The church is as yet in an unfinished state, the chancel, organ chamber, and south aisle having yet to be built; but the nave, two aisles of six bays, and south porch having been satisfactorily completed, it was thought advisable to have the building consecrated for divine service. The cost of the church so far amounts to about £3,000. In a few months the building of the chancel will be proceeded with, a work which is expected to cost £1,500. The church is built of brick, with stone dressings. The seats are of dark stained wood, and accommodation is intended in the whole church for 750 persons, the portion already built accommodating about 500. The architect is Mr. C. Hodgson Fowler, F.S.A., M.A., Durham; and Mr. W. Bastiman, Linthorpe, Middlesbrough, is the sole contractor.

MOLD.—A new English Presbyterian church and schools are erected on a site near the railway station. The style of the building is Gothic, and it will seat over 450 persons. The front portion is semicircular on plan, and the sittings are arranged in a gallery form, with stepped aisles leading to the body sittings. The school buildings are at the rear, and contain, on the ground floor, a schoolroom to accommodate 200 persons, three class-rooms, and a minister's vestry, with conveniences. A large schoolroom is constructed over the latter, capable of seating 250 persons, the access to same being from separate staircase and entrance in Westminster-road, with doors opening outwards for cases of emergency. The main feature of the building is a tower placed at the angle of Chester-street and Westminster-road, which is square at the base and tapers in an octagonal form to an octagon stone spire. The contractor is Mr. Thomas Roberts, Wrexham-street, Mold; the clerk of works being Mr. John Roberts, of Ruthin. The architect is Mr. T. G. Williams, 3, Cable-street, Liverpool.

PRESTON.—New Central Industrial Co-operative Stores erected at the junction of Lancaster and Ormskirk-roads were opened on Friday. The buildings cover an area of 300 square yards, and, exclusive of cellars, are three stories high, with store-rooms, in addition, in the roof. The ground floor, 14ft. in height, is arranged as three shops. The first floor rooms over the three shops will be used as showrooms; they will be reached by a pitchpine staircase, with mahogany newels. All the fittings and joinery on these floors are of pitchpine. The workrooms on the second floor

are approached from the back by a separate staircase. The basement cellars have floors finished in concrete, and lighted with Hayward's semi-prism lights. The buildings are heated throughout with hot water on the low-pressure system, and ventilated by vertical inlet tubes, air-extracting flues, and Boyle's air-pump ventilator. The elevations are treated in the Renaissance style, with piers, caps, arcading, and cornices on the ground floor, executed in York stone. The remaining portions of the elevations have been carried out with Edwards's Ruabon red pressed bricks. The buff terracotta work throughout, as also the enriched and modelled work, was supplied by the Leeds Fire Clay Company, Limited, from their Burmantoft works. The mosaic floors in the entrance vestibules have been provided and laid by Messrs. Craven, Dunnill, and Company, Limited, of Jackfield, Shropshire. All the remaining trades were executed by Mr. John Walmsley, of Theatre-street, Preston, to whom the contract was let. The stores have been erected from designs prepared by Mr. William D. G. Mumford, architect, 33, Guildford-street, Preston, and under his personal superintendence.

RAWDON, WEST RIDING.—A new Baptist chapel at Rawdon, adjoining the Sunday-schools erected in 1884, was opened on Wednesday week. It is of the modified Classic type that prevailed in the middle of the last century. It is 78ft. by 37ft. and 27ft. in height, with two shallow transepts that may be extended when further accommodation is required. There is an end gallery three seats deep, approached by a staircase from the vestibule. At the opposite end there are the organ recess, the seats for the choir, the baptistery, and the pulpit, together with vestries. Two large rooms are provided over the vestries for young men's classes. These rooms, as well as the chapel, have direct communication with the schools. The chapel seats 450 worshippers. The external walls are of tooled ashlar and dressed stone. The pulpit and pews are of polished pitchpine. The works have been carried out under the superintendence of the architects, Messrs. T. H. and F. Healey, of Bradford. The contractors for the various works are:—Messrs. W. Fleisher and Sons, masons; Mr. J. Taylor, joiner; Messrs. G. and R. Nunn, plumbers; Mr. Dixon, plasterer; Mr. J. Richardson, slater; and J. Roome, painter. The cost, including furnishing, amounts to £3,600.

CHIPS.

The Wesleyan chapel at Epsom has been reopened after enlargement, at a cost of £2,000. The style is that of Early English. The additions comprise new aisles, chancel, organ-chamber, ministers' vestry, enlargement of the store-room, tea-room, and warming-chamber. The church now seats nearly 400 persons. Mr. George Gray, of High-street, Egham, has carried out the contract, from the design of Mr. James Weir, of Victoria-street, W.

Chacewater Church restoration draws near its completion, and the date for reopening has been fixed for Tuesday, 20th December. The work has been carried out from the designs of Mr. Edmund Sedding, architect.

The new town-hall at Kilmaurs, N.B., was opened on Friday. The building is a two-storied edifice in front, with the hall proper running back at right angles to the front elevation. On the ground flat of the frontage are situated the janitor's house and a public office. A staircase gives access to a reading-room and recreation room, which occupy the whole area of the second flat. The hall proper is 58ft. by 30ft., and 20ft. high, and is seated for 450 persons. The architect is Mr. M'Houll, Kilmaurack.

The scheme for the bridging of Alcaig Ferry was discussed at a joint meeting of a committee of the town council, when it was agreed that the scheme should be proceeded with, and Mr. Fraser, C.E., Inverness, was instructed to prepare plans and specifications. The Alcaig Ferry is at the head of the Cromarty Firth, which separates the Black Isle from Dingwall, necessitating a journey of about six miles to those who wish to come into the town. The part of the Firth which is to be bridged is three-quarters of a mile broad, and the estimated cost is from £8,000 to £10,000.

The architectural classes of the Glasgow and West of Scotland Technical College have been sketching and measuring in the Glasgow Cathedral during the Saturday afternoons. Visits have been paid to Queen Mary-street and Dalmarnock-road new public schools, where 60 students attended; while on Saturday last 70 students were present at the visits to the new portion of the Victoria Infirmary.

Engineering Notes.

DOVER.—Application will be made next session for powers to construct a marine drive and promenade between Dover and St. Margaret's Bay, a distance of between three and four miles. The undertaking, which is due to private enterprise, is estimated to cost little short of £200,000. It contemplates the blasting of a portion of the high cliffs, and the building of a sea wall in order to obtain building sites besides a marine drive, the situation having a southern aspect. In addition to this the Corporation have decided to continue the policy of street improvements in the heart of the old town inaugurated last year, and also to apply for further powers to enable them to make a new thoroughfare, and to widen one of the main arteries of the town, the cost of which is estimated at £50,000 or £60,000. A contract for £415,000, has also just been entered into for the first portion of the new harbour, which will cost at least another quarter of a million to complete; and the South-Eastern Railway Company have obtained powers to acquire a large extent of property at the western end of the town for erecting a new terminus.

CHIPS.

Mr. Usill's paper, which, as advertised on our front page, was to have been read at the meeting of the Society of Architects next Tuesday, is postponed, owing to that gentleman's ill-health. Some other paper will be found no doubt before Tuesday.

At Worcester, on Friday, a builder named Sumner was sentenced to eighteen months' imprisonment for soliciting a man to set fire to the prisoner's property with intent to defraud an insurance company.

At Stonehouse Bankruptcy Court on Nov. 16th, before Judge Edge, the application of John Reed, builder, Plymouth, for discharge, was further adjourned for six months, owing to the difficulty of winding up the estate.

The organ in Hereford Cathedral, which for a long time has been undergoing restoration and extension, under the direction of Messrs. Willis, was reopened on Tuesday. The cost has been over £2,000.

An organ has been erected in Mayfield Parish Church, Edinburgh, at a cost, with its accessories, of nearly £1,000. It is by Messrs. Brindley and Foster, of Sheffield, and occupies the north transept.

The ventilation of the new laboratory, Queen's College, Belfast, is being executed by Messrs. Baird, Thompson, and Co., London and Glasgow, their patent "Grahtrix" ventilators being used for the extraction of the vitiated air.

Next session a Bill is to be introduced seeking powers for the construction of an underground electric railway, commencing close to Clapham Junction and passing thence *via* South Kensington, to a point near the Great Western Railway Company's terminus at Paddington. The proposed railway is an extension in the direction of Clapham Junction of the South Kensington and Paddington Subway scheme, which was promoted in 1891, but withdrawn.

Messrs. Stephens, Bastow, and Co., Limited, of Montpellier, Bristol, have received orders for the erection of additions to the Marlborough College, at a cost of £12,600. The same firm built the chapel for the same college, under Messrs. Bodley, A.R.A., and Garner, Gray's Inn, London, who are the architects for the present work.

In consequence of the application of the Evesham Town Council for sanction to borrow £1,550 for works of sewerage disposal, a Local Government Board Inspector, Mr. F. H. Tulloch, A.M.I.C.E., conducted an inquiry into the subject matter of the application at the Town Hall, Evesham, on Friday. Evidence was given by Mr. T. Cox (town clerk) and Mr. Candy, who explained the ferocious and polar process of sewage, which it is proposed shall be adopted, followed by filtration.

A new Wesleyan chapel was opened at Bideford on Friday. The treatment is Classic, and the chapel seats 1,015 people. The building is about 70ft. by 50ft. The whole of the seats are arranged at such an angle that every sitter faces the preacher. The seats, stairs, rostrum, and other woodwork are of pitch-pine. Local stone is used for the building, with Bath stone dressings. The architects are Messrs. Habershon and Fawcner, of London, Newport, and Cardiff; and the contractors Messrs. Cock and Lamerton, of Bideford. The cost of the undertaking—which includes the transformation of the old chapel into schoolrooms—is estimated at about £6,000, of which the new chapel, for building and fittings, will absorb about two-thirds.

Correspondence.

"THE COUNCIL BROADWAY."

To the Editor of the BUILDING NEWS.

SIR,—In the article entitled "The Council Broadway," in your issue of the 19th inst., you state that it appears to you "that such an important question as the approval of designs should be left to a small representative committee of the greatest architects of the age, and that such a committee (say of three) should be drawn from the ranks of the Royal Academy and the Royal Institute of British Architects."

There are several objections that might be raised to this proposal. It is, firstly, a matter of grave doubt that it is possible to draw from the ranks of the Royal Academy, and more especially the Royal Institute of British Architects, the "three greatest architects of the age."

Do paying a small annual fee, and passing the Institute examinations (which nearly, or probably all, the leading members escaped by joining before the examinations were instituted) constitute the qualifications of a leading architect? Why should not a man who has not paid the above-mentioned fees to be enrolled on the books of the Institute be equally competent with any F.R.I.B.A., or even the President himself, to act as a member of the suggested committee? It must by no means be supposed that the confidence you repose in the Institute is universal.

The *Spectator* of November 19, in an article on the "Royal Institute of British Architects and its Critics," states that "The best English architects of our day are almost, without exception, to be found outside the Institute. To anyone with a knowledge of the art it is enough to name Messrs. Norman Shaw, John Bentley, G. F. Bodley, Philip Webb, T. G. Jackson, and Basil Champneys."

That this view is common among a large number of architects is shown in the circumstance that they withhold themselves from the Institute.

—I am, &c., CHARLES C. ROBIN.

357, Liverpool-road, N., November 22.

VICTORIA CATHEDRAL COMPETITION.

SIR,—My attention has been called to some paragraphs in the BUILDING NEWS referring to the above competition. May I be permitted, through the medium of your valuable paper, to say a few words on the subject to those who are interested in that competition?

There was a desire, in framing the conditions, to secure a perfectly fair trial, and to avoid those errors which had been repeatedly pointed out by professional men to have occurred on similar occasions. The selection of our professional assessor, Sir Arthur Blomfield, was strictly adhered to. The order of merit of the three premiated designs was "Fides," "New and Old," "Ars." With reference to the first of these, the assessor's actual words in his report were:—

"The plan is in most respects better considered than that of any other, and seems to provide all that is wanted in a church of this size, which has to combine the requirements of a cathedral with those of a parish church."

"The appearance, both externally and internally, would be sufficiently imposing and effective."

"It appears to me to be more free from obvious defects than any other."

These quotations will, I think, justify the committee in their choice. Speaking from the point of view of a mere amateur, and with great reverence for the opinion of properly qualified specialists, I must say that while all three designs appeared to me greatly superior to the others submitted, and, while each exhibited interesting features and advantages not possessed by the other two, that of "Fides" certainly seems best adapted to the purpose for which we wanted it, and the site which the building has to occupy.

"New and Old," if deprived of its elaborate and beautiful accessories, would lose half its charm, and is really, if I may be allowed the expression, too "bizarre" for a colonial cathedral.

"Ars" does not provide on plan such facilities as those afforded by "Fides," though no one can fail to appreciate the general beauty of mass in its elevation.

"Fides" has a sober, dignified exterior, securing the most that can be obtained of cathedral-like effect with the limited funds at

our disposal; and I feel sure that anyone who is familiar with Gothic buildings on this side of the Atlantic will be thankful for such an addition to existing specimens of church architecture.

In conclusion, I must tender the apologies of the committee for delays which, though aggravating to competitors, were unavoidable.—I am, &c.,

ARTHUR BEANLANDS,
Canon and Rector, Christ Church Cathedral,
Christ Church Rectory, Victoria, B.C., Nov. 4.

DIVISION OF BUILDINGS.

SIR,—You will, I am sure, allow me to point out a mistake in the latter part of your article of last week under the above heading.

The question at issue in the case referred to had nothing to do with the thickness of walls, nor was it at all the question, "What is a warehouse?" It is fully and fairly set out in the whole of the article except the last paragraph, and as the matter is still under notice of appeal, I will not refer to it further.

But I do wish emphatically to contradict the statement that the alleged irregularity was not discovered until the building was far advanced. As soon as I saw the plans at the commencement of the works, I wrote both to architect and builder, pointing it out, and as soon as I could legally serve the notice to amend I did so, and the subsequent proceedings took their usual and proper course.—I am, &c.,

THE DISTRICT SURVEYOR.

96, Gower-street, Nov. 22.

MOVING MASONRY HOUSES IS ECONOMICAL.

SIR,—There seems to be a lost opportunity just now occurring of providing cheap central housing for a number of workmen. Two houses, of four stories above ground level, in Great Russell-street, which, it is stated, were newly built within the last 30 years, are now being pulled down to make room for larger houses on the "flat" arrangement. If these two houses were moved bodily back on the rear of the same plot, or to an adjoining plot on Gilbert-street, which would only cost about one-fourth of similar new buildings, taking account of the rental value of the extra time which the latter would consume, an opportunity for cheap rents could thus be obtained.

It seems that architects and contractors undervalue the progressive tendency of bodily house moving by wrongly considering that it will deprive them of so much work; but they thus overlook the fact that the dead loss which pulling down houses entails is often a serious barrier to substituting buildings of a better class on their sites.

If "housebreakers" added to their vocation that of bodily house moving, and the London County Council had the power to permit such removals without undue inconvenience to the public, there might be some prospect of reform in this line. It would also be a check upon the "improvement dodge" of some unprincipled house owners, who are disposed thus to pick the public pocket when new thoroughfares or streets are proposed for public convenience.—I am, &c.,
A. B.

THE TROUBLES OF A PARSON WHO UNDERTOOK TO BE HIS OWN ARCHITECT.

SIR,—Many of your readers will read the following clippings from one of the best-known newspapers in the West with interest:—

Western Morning News, Tuesday, Nov. 15, 1892:—

The circular ribs, trusses, pitchpine, chancel screens, choir stalls, and seating, used in the restoration of Bradstone Church, were supplied from the Eagle Steam Joinery Works, Plymouth, and the work was carried out under the superintendence of Mr. John Oliver, Weire House, Lifton.

Western Morning News, Nov. 18:—
BRADSTONE CHURCH.

SIR,—With reference to the paragraph which appears in your issue of to-day, I beg to state that the only truth contained therein is that the woodwork mentioned was supplied by the firm named. This fact was stated in the account furnished by a friend of the opening of the church, and doubtless was accidentally omitted by you, as was another thing—viz., that Aspinall's water paint was most successfully used in the decoration of the chancel.

I supplied the designs for the whole of the woodwork, which, though roughly given, were ably caught at and carried out by the foreman of the Eagle Steam Joinery Works. I superintended the whole work. The seats were fixed by workmen from Lifton Park. The screen and choir fittings by George Gidley, the able workman of Mr. Bariball, of Lewhitton. John Oliver is a worthy and

good plasterer and mason, and did his work to my satisfaction. But not a day passed without my superintending his work. Since names have been mentioned, I ought to add that the decorations of the chancel were the work of Mr. Bennett, of Launceston.—Yours truly,
November 15.
THE RECTOR OF BRADSTONE.

Western Morning News, Nov. 17:—

Sir,—In reply to the letter of the Rector of Bradstone, appearing in this morning's issue of your valuable paper, I think, in common fairness to myself, it should be known that the whole of the restoration work done in connection with the above church, with the exception of that in the chancel and one small doorway in the church, discovered as the work proceeded, was carried out by me, under a contract between the rector and churchwarden of the parish and myself, and having Mr. Bullen, the estate carpenter of Lifton Park, nominated in said contract as the one to finally approve and adjust the account, and who has done so, and is quite satisfied with my carrying out.—Yours truly,
JOHN OLIVER.
Weir House, Lifton, 16th November, 1892.

Western Morning News, Nov. 18:—

Sir,—I write with the contract of "John Oliver, of the Weir Cottages, Lifton," before me, which has only to do with pointing, plastering, and colouring, with the exception of a new west door and a piece of flooring which were done for him by Mr. Barriball of Lawhiton. John Oliver in his first estimate was so far out of reckoning that it was agreed that Mr. Bullen, employed for long years at Lifton Park, and well known as a very able man, should measure up the work. There is no proviso that it should be done to his satisfaction.

John Oliver is completely wrong in saying that a small doorway was discovered during the process of the late works. I discovered this, which led originally to the roof-loft, and an old south doorway nearly five years since, when Mr. Yole, of Treadwell, was doing work in the church for me. If John Oliver had not claimed that to which he has no right, which put all others employed by me completely in the background, I should not have noticed his ridiculous paragraph in your issue of Tuesday last.
THE RECTOR OF BRADSTONE.

Western Morning News, Nov. 19:—

Sir,—Allow me to correct the Rector as to his observations in your valuable paper to-day which he says has only to do with pointing, plastering, and colouring, which is not correct. I will now give you an outline of my contract. Firstly, take down old boarded ceilings to north and south aisle, point slate roofs, replaster same, re-dress interior of tower and point same, clean off and re-dress column arches and point same, clean and re-dress porch and point same, repair and fix new steps to entrance gates, take up old flooring and relay new in south aisle, new pitch-pine tower door with oak fronts, refix font, repair plaster and colour interior of church, all roofs stained and varnished; secondly, re-seat the whole interior of church from plans prepared by an Exeter builder, who gave a price from same for £43, which was not accepted by the Rector, but the same plans, with an addition of improved seat ends, taken from a periodical, which, after some consideration, was accepted from me. For all of the above work the men were employed and under my charge, and paid by me. Respecting the Tuesday's paragraph in your paper, I know about it. Respecting my prices, they have not been altered from the first, and I consider Mr. Bullen was nominated to overlook the work in consideration of the Lifton Estate giving the sum of £40 towards the restoration.—Yours obediently,
JOHN OLIVER.
Weir House, Lifton, November 18th, 1892.

Western Morning News, Nov. 21:—

Sir,—John Oliver's letter is a tissue of exaggerations, and grossest misrepresentations, and as such is unworthy of further notice by me.
THE RECTOR OF BRADSTONE.

I might add to this story of a storm in a teacup that, according to Crockford's "Clerical Directory" for 1892, the rector of Bradstone is the Rev. Neville George Murray Lawrence, M.A. He has held the living since 1887, before which he was successively English Chaplain at Toulon and Freiburg.—I am, &c.,
Exeter, Nov. 21.
HARRY HEMS.

The Ryton-on-Tyne local board have just appointed a surveyor in the place of the late Mr. Salter. There were upwards of 100 applicants, and the board have selected Mr. John Palmer Dalton. The new surveyor has been for several years assistant surveyor at Jarrow. His father was one of the pioneers of the movement for establishing local boards in North Durham, and his brother is clerk to the Blaydon and Benwell local boards.

A meeting of a committee of the town council of Arbroath was held on Monday with regard to the destruction of the parish church by fire on Monday week. It was resolved, before doing anything in the matter, to take the opinion of eminent counsel, particularly in view of a decision which was given in the Court of Session in 1883 by Lord McLaren in a case which was raised by the minister of the parish claiming a glebe. In the decision referred to, which became final, his lordship refused the minister's claim, on the ground that the church of Arbroath is a purely burghal church. The congregation have meanwhile obtained accommodation in Ladyloan *quod sacra* parish church. The object of the present memorial is to ascertain whether or not the church is purely burghal, with the view of determining the obligation of the magistrates and community as to its restoration.

Intercommunication.

QUESTIONS.

[10892].—**Building Societies**.—I shall be glad of information as to the law of the State of New York, whereby the Government have the power to send an inspector to any real estate company, having an office or carrying on business in the State of New York, with authority to inspect the books and affairs of the company, and to test the value of the securities; and the society or company failing to give satisfaction to the inspector, such company is immediately closed, so far as New York State is concerned, under heavy penalties.—ROBERT MELLORS, Bridlesmith Gate, Nottingham.

[10893].—**Floor Boarding**.—The boarding for a house was specified, amongst other things, to be wrot and 1 1/2 in. thick. The builder has supplied boarding which is exactly 1 1/10 in. thick, which he says is the 1 1/2 in. boarding of the trade. I should be glad to know if there is any such trade understanding, or whether I can reasonably compel him to put the full thickness.—ARCHITECT.

[10894].—**Soiling Bricks**.—In the manufacture of London bricks, the clay is soiled—i.e. mixed with domestic ashes. Where these are unattainable, what other substances are used, in order of merit, to effect the same purpose?—L. H.

[10895].—**Lime**.—Given a limestone, how to ascertain the quality of lime which would be produced therefrom, and whether suitable for building or not. Also, to determine the class of stone, whether magnesian or otherwise.—L. H.

[10896].—**Assessment**.—I wish to read up the law and practice as to poor-rate assessments and appeals therefrom. Can anyone refer to books and authorities on the subject?—NOVICE.

[10897].—**Sgraffito**.—May I ask some reader to inform me where I can get full information for decorating with sgraffito? Are there any works published on the art, and is it very expensive?—NORTHERN STUDENT.

[10898].—**Rats**.—Can any of your readers give me information as to the best way of getting rid of rats in old walls and floors?—SUBSCRIBER.

[10899].—**Damp**.—I have recently erected a brick house, the outer walls being 1 1/4 in. thick, faced with pressed brick. During the late driving rains the water has come through the whole surface of the east wall. I should be glad of suggestions as to treatment. Is there any preparation which will leave the brickwork its present colour, and without glaze?—SUBSCRIBER.

[10900].—**Stoneware and Earthenware Pipes**.—Will one of your numerous readers kindly inform me what is the difference between stoneware and earthenware pipes? Will the same clay which is used for earthenware pipes do for stoneware?—FIRE.

REPLIES.

[10893].—**Position of Timber**.—I have to thank Mr. Harris for his last reply, p. 652; but in it he uses a much less definite description of the sap-valves than he did in his first on p. 478. Now he calls them "sap-valves or pores"; but surely valves and pores are two different

things. His original statement was: "The reason for placing staves inversely to their natural position in the tree is because the sap-valves open upwards from the root, and when thus reversed they prevent the ascent of moisture in the wood." This appeared to point to an arrangement similar to that of the valves found in the veins of the human subject, which prevent a back current in the venous blood. The wood of the ash having been pointed out as one of those where the sap-valves could be seen, I have examined numerous specimens of that wood, preparing them, however, neither with "saw" nor "axe," but, as usual, with a keen razor. Even that is all too clumsy an implement for some of the delicate membranes of the tissues. My search for the "sap-valves opening upwards" has been unsuccessful; but, bearing in mind the difficulty of proving a negative, in my opinion, all the evidence pointed to the conclusion that they are non-existent in any of the numerous specimens I have had under examination, taken from all parts of the section, from the pith to the

bark inclusive. At this point I feel that you, Sir, may reasonably cut short my story; but should you be willing to allow your readers to see the kind of evidence on which my conclusion is based, I send a drawing of a longitudinal section of one of the "valves or pores" indicated in Mr. Harris's sketch on p. 652. The section is cut tangentially to the dark radial lines, which are so conspicuous in a transverse section—the "medullary rays" of the botanists. I withhold other drawings as unnecessary for the present purpose. They were all made, with the aid of a reflector, from sections of the wood placed on the stage of a microscope; and the scale, by which the actual size of the parts can be measured, was drawn in like manner from a micrometer placed in the same position. The section of wood from which the drawing was made displayed an uninterrupted length of six cells or divisions of the so-called "valves or pores" one of which, with parts of two others, are included in the drawing. The cells average about nine-thousandths of an inch in length, and are lined with a membrane covered with dots of exceeding minuteness—the "pitted tissue" of the botanists. The cells are sub-cylindrical in cross section, and are joined end to end. The ends are sometimes square with the sides; but more frequently oblique, as in the drawing. These ends are originally complete, and form a true partition—the "septum" of botanists—between the adjacent cells. I found many instances where the end-walls of the cells were quite perfect, and the line of junction between clearly defined. In other cases these end-walls had been absorbed, leaving only a ring projecting round the inside of the cells. This absorption is somewhat capricious, and the series of six cells above-mentioned is a case in point, for of the five junctions between them three are perfect; but in the other two the rings only remain. In the drawing I have shown a cell which has its upper end complete, but at the lower end the walls have disappeared. I presume that it is at these septa that the "valves opening upwards" would be seen if anywhere, but I found no indication of such an apparatus, either in these or any other of the structures examined. The large pitted cells, as shown in the drawing, are embedded in a mass of elongated-cigar-shaped cells, pointed at the ends, composed of sparsely-dotted tissue, and densely packed together—the "woody tissue" of botanists. The squarish dotted cells show where the razor has cut across the medullary rays which extend radially from the pith to the bark. In sections cut parallel with these rays they constitute the "silver-grain" of the workman. The dots in these small cells do not represent pitted tissue, but a granulated substance with which they are loosely filled.—E. S.

[10873].—**Boasting**.—I am sorry to have aroused "A Mason" by my reply in this matter, and am always glad to be corrected, even when done in the manner of a week ago. However, I must be proved wrong (and authorities quoted) before I admit that "A Mason" knows very much about his business. In the first place, let me advise him to consult a dictionary of terms before correcting the orthography of the querist, and those of us who answered. In all the authorities I have been able to consult, Weale, Parker's "Glossary," "Cyclopaedic Technical Dictionary," "The Dictionary of Architecture" (issued by the Architectural Publication Society), Nicholson's "Cyclopaedia," and many back volumes of the Building News, the word is spelt as above, and not "boasted." Can "A Mason" quote any rebutting authority? Second, as regards the width of the chisel, the "Architectural Pub. Society's Dictionary of Architecture" (Vol. I.) defines "boaster, a chisel 2 in. wide in the cutting part, being one of the tools used by masons." Nicholson's "Cyclopaedia," 1859 ed., says that a "boaster or boasting-tool" is from 2 in. to 2 1/2 in. or 3 in. in breadth. Can "A Mason" refer to any authority where it is stated that the chisel is 4 in. up to 5 in. wide? Third, as regards the angle, I will withdraw the term "incompetent," and will observe that many men show idiosyncrasies in their workmanship, and the methods in different districts vary. Fourth, "A Mason" is asking us to believe too much when he says that the custom he mentions prevails "in the Midlands and North of England." This is too large an area of ground for any custom to prevail over. Is not herring-bone boasting common in Derbyshire? Is the term "boasting" ever mentioned in Cumberland or Northumberland specifications? Now, as regards the custom in the Manchester district, I have this week visited two stone-working yards, and asked to see a boasting-tool. I was shown in one case a chisel 2 1/2 in. wide, and in the other 2 in. wide. I then asked for a sample of boasting, and in both cases vertical marks were made, though upon asking whether they were made sloping, I was told that it was just as was directed by the architect or clerk of works. I asked for a boasting tool 4 in. or 5 in. wide, and was informed that they never used any wider than 3 in. In conclusion, let me say that I do not intend to argue the matter with "A Mason" unless he quotes reliable authorities.—THE ONE WHO TOLD.

[10881].—**Severn Tunnel**.—In reply to "Doubtful," the best information I am able to obtain as to the sort of bricks in which the arching of the Severn Tunnel is executed is contained in the following extract from "The Severn Tunnel: its Construction and Difficulties," by T. A. Walker, the contractor. He says, on p. 177: "No less than 78,450,000 bricks were used in the construction of the tunnel and bridges. These bricks were vitrified bricks, from the Catfircrook Brick Company, near New Passage, on the Bristol and South Wales Union Railway, from the Fishponds and Bedminster Company, near Bristol, from Staffordshire, and from our own brickyard, near the five-mile-four-chain shaft." If "Doubtful" can obtain the perusal of this book, I will promise him more romance and hair-breadth escapes than are contained in a hundred ordinary novels. In the current volume of this journal (July 29th, 1892, p. 140) will be found an account of the behaviour of the brickwork under the enormous pressure exerted by the external water. A description is given in an appendix to Mr. Walker's book (page 180); a description is given of the pumps, both temporary and permanent, and their positions. The temporary pumps numbered 80 at 9 pumping stations, and capable of raising 84 million gallons in the 24 hours; the permanent pumps numbered 16 at 6 stations, capable of raising 66,000,000 gallons per day; these, however, are not all at work regularly, some being in pairs working alternately, some only during wet weather, and others only in the winter season. "Doubtful" will find an article on the tunnel in the Building and Engineering Times.

for August 30th, 1884, and also a paper by Mr. T. A. Walker, read at the British Association Meeting at Manchester, and reported in *Engineering*, Sept. 9th, 1887, page 290.—**DEPUTY B.E.**

[10884].—**Framing.**—In Rivington's "Building Construction" (Part II. p. 416), "R." will find the following remark:—"Fine sand is sometimes thrown on to the last coat while it is wet, with a view to imitating the rough surface of stone." Of course, the last coat of oil paint is intended.—**GILBERT W.**

[10885].—**Ants.**—Dryness and warmth are conditions suitable to ants. Unless you can alter the conditions you are bound to be troubled with them.—**C. F. M.**

[10885].—**Ants.**—In "Enquire Within upon Everything," paragraph 2226, "Bothered" will find the following methods of destroying ants given:—"Drop some quicklime on the mouth of their nest, and wash it in with boiling water; or dissolve some camphor in spirits of wine, then mix with water, and pour into their haunts; or tobacco-water has been found effectual." Has "Bothered" tried the above? Another method is to make a mixture of tar and water, and pour into the nest. Inside the bakehouse the following might be tried:—Mix arsenic, sugar, and water in a plate; cover with a slate, leaving room for the insects to pass between slate and saucer. Lay a stone on the slate, and take all precautions to prevent any creature but the ants getting at the poison.—**GILBERT W.**

[10886].—**Breaking Weight.**—If $D = 8$ in. and $L = 12$ ft., then $BW = 221 \cdot 81$ tons. To reverse the problem and find the value of D we retain the same notation, and transposing we obtain—

$$D^4 = \frac{BW \times L^2}{781}$$

from which $D = \sqrt[4]{\frac{BW \times L^2}{781}}$

The value for BW should not be less than ten times the weight to be supported. "Student" does not state at what point of the beam the stresses are required. If at the centre of the span, under the conditions given, the formula would be $\frac{WL}{8D}$. I cannot determine whether

"Student" means his beam to be *encastré* or not. It is not usual to make any allowance for the web, and the omission besides is on the safe side. "Student" will find this question of "web" very ably treated in your articles "Iron Arches of Long Span."—**ESSEX.**

[10886].—**Breaking Weight.**—(1) This question formed part of the R.I.B.A. Exam. in March this year. The formula—

$$W = \frac{a \times d^4}{l^2}$$

is adapted only for pillars over 30 diameters high, which gives the resistance to bending (that force coming into action before crushing takes place). In pillars over 10 diameters and under 30 diameters high the strain is one of bending and crushing; therefore the formula for the breaking weight is—

$$BW = \frac{W \times C}{W + \frac{1}{2}C}$$

When $W =$ Breaking weight for pillars over 30 diameters high, in tons.

$BW =$ Ditto ditto over 10 and under 30 diameters, in tons.

$d =$ Diameter of the pillar in inches.

$l =$ Length in feet.

$C =$ Crushing strength per square inch (for red deal 3 tons).

$a =$ Constant number (for red deal 781).

Therefore, for a pillar 8 in. by 8 in. by 12 ft.—

$$W = \frac{781 \times 4,096}{144} = 222 \text{ tons.}$$

$$BW = \frac{222 \times 192}{222 + 144} = 116 \text{ tons, or } 11 \cdot 6 \text{ safe load.}$$

(2) To obtain the diameter of a pillar when the weight and length are known from the formula $W = \frac{a \times d^4}{l^2}$ take d out of the equation, and invert the values—

$$d = \sqrt[4]{\frac{W \times l^2}{a}}$$

Since the strength of a beam uniformly loaded, with the ends fixed, is to a beam similarly loaded, but with the ends loose in the proportion as 3 is to 2, the formula $W = \frac{WL}{12d}$ is correct.—**R. J. ANGEL.**

[10886].—**Breaking Weight.**—By the formula given—

$$BW = 781 \frac{D^4}{L^2} = 781 \times \frac{8^4}{12^2}$$

= 222.15 tons, which is far too high a figure. A better formula is that of Shaler Smith, where—

$$W = \frac{5000}{1 + \left(\frac{8}{B} \times .004\right)}$$

$W =$ breaking load in pounds per square inch of area of a post of yellow or white pine.

$B =$ length in inches squared.

$B =$ breadth in inches squared.

By this formula the 8 in. square post should bear—

$$W = \frac{5000}{1 + 2.736 \times .004} = \frac{5000}{64}$$

= 2177 lb. per square inch.

As the sectional area of post is $8 \times 8 = 64$, the breaking weight will be—

$$\frac{2177 \text{ lb.} \times 64}{2240} = 62.2 \text{ tons.}$$

If the post were round, calculate as for a square post, and divide by 1.7 for breaking weight. To reverse this formula, having given length of post and breaking weight,

use a method of trial and error, assuming a section and calculating what it will bear until the right one is found. A factor of safety of 10 should be used for wooden struts. For the rolled beam the formula $\frac{WL^2}{12}$ gives the greatest

bending moment (which is at the supports) for a beam fixed at both ends and uniformly loaded. This must be equated to the moment of resistance which approximately = area of flange \times limiting stress allowable \times full depth of beam. Take the units the same in both equations, pounds or tons, inches or feet.—**SIGN SENG.**

[10887].—**Cubing Buildings for Approximate Cost.**—The following is the method I adopt, and one usually observed. Take the main block of buildings which is roofed to a certain height and has about the same character of design, and measure length and breadth, multiplying them together as a superficial out to out of walls, though neglecting small projections like bay windows or small projecting parts. Then for height take to bottom of footings to half-way up the roof, irrespective of the pitch. If there are lower buildings or offices of plainer workmanship attached, their contents should be separately taken at a lower price per foot cube and added to the cost of the main block. Some architects take from bottom of footings to plate level, thinking the space below ground equivalent to the roof.—**G. H. G.**

[10887].—**Cubing Buildings.**—The proper method of abstracting the cubical contents of a building is to measure from the bottom of the footings to the top of the plinth, and multiply by the length and breadth at that level. Then take another calculation for the upper portion, measuring from the top of plinth to a point half-way up from the wall-plate to the ridge of the roof by the length and breadth at that level. All horizontal measurements are taken from the outside surfaces of the wall. Projections such as porches, bays, oriels, &c., are cubed separately and contents added to the previous results. Flat roofs are measured to the top of the parapet walls, except in cases where they are exceptionally high. Then a reduction per cubic foot in the cost will balance it.—**R. J. ANGEL, Birkenhead.**

[10888].—**House Drainage.**—A ventilating-pipe should be brought up from the cesspool above ground, so as to allow the gases as they accumulate to escape, and to relieve the pressure. If the house-drains are disconnected, so much the better, as any foul gas from the cesspool would escape at this point instead of entering the house. By inserting a ventilating-pipe in the cesspool a current of air will be set up between the disconnecting-chamber and the ventilator, and no gas can then accumulate.—**G. W. C.**

[1089].—**Surveyors' Charges.**—It is usual for the surveyor to charge half to the client and half to the builder for measuring up the work; and in this case for both building owner and builder to pay their respective surveyors.—**G. W. S.**

[10891].—**Covered Way.**—Permission to erect a covered way over a private yard connecting two buildings is required.—**G. W. S.**

CHIPS.

The funeral of Mr. John Scrivener, builder, of Warley-road, Brentwood, who died at the age of 58, took place in Warley cemetery on Friday.

A singular mishap occurred in St. Paul's Cathedral at noon on Tuesday. The man who winds up the clock had just completed his work when one of the weights, which scales about 800 lb., fell through the timber supports of the clock, and crashed through the tower staircase. Happily no one was hurt.

Mr. Joseph Broadberry, who has just been appointed a justice of the peace for Lincoln, is foreman over one of the workshops at Messrs. Clayton and Shuttleworth's Stamp-end Works, and is the first working-man magistrate who has sat on the bench in that city.

At Coseley parish church on Thursday in last week, the bells which have been re-cast by Messrs. Mears and Stainbank, of London, were rededicated.

Mr. T. J. Moss Flower, C.E., Cert. Mem. San. Inst., has been appointed surveyor and sanitary inspector, subject to the approval of the Local Government Board, at Portishead, near Bristol. There were numerous applications for the post. Mr. W. E. Jones, F.R.I.B.A., and Mr. Moss Flower were left in the final selection. The latter gentleman was recommended by the general purposes committee, and the appointment was confirmed by the board. Mr. Moss Flower still continues his private practice at Carlton Chambers, Bristol.

The Bishop, Dean, and Chapter of Ripon are taking steps to erect a reredos in Ripon Cathedral in harmony with the style of the choir.

The first of a series of lectures on sanitary science, which are being promoted by the Shipley Local Board, was delivered by Mr. W. Spinks, A.M.I.C.E., in the Co-operative Hall, Shipley, Yorks, on Tuesday week. The lecturer showed the dangers to health that arose from defective drainage.

The old bridge across the river Clyde, at Rutherglen, Glasgow, known as Rutherglen Bridge, is about to be taken down and replaced by a handsome granite bridge of three spans, of 90 ft., 100 ft., and 90 ft. respectively, and having a width of 60 ft. between the parapets. The new bridge has been designed by Messrs. Crouch and Hogg, C.E., Glasgow, and the contract has been let to Messrs. Morrison and Mason, Limited, the price being nearly £63,000.

Legal.

WHAT IS A "SKY SIGN"?

NO sooner do we get a statute regulating the use and abuse of sky signs, than cases arise in which the Courts are asked to say what is a "sky sign" in accordance with the Act obtained by the County Council of London, the Sky Signs Act, 1891. The definition given in that statute covers any representation in the nature of an advertisement, put up wholly or in part over any house or building, and which is visible against the sky from the street; and it is provided that it shall be unlawful to retain any sky sign previously existing, except under license from the County Council. Two cases have lately been taken to the High Court, in which this statute had to be construed. The first arose about a windmill put up by Carwardine and Co. (*Times*, November 2) upon and over their house in the City-road. The contention of the owners was that this structure did not come within the Act at all, as it was primarily intended and used to grind meal, generate electricity, and hoist sacks. But it appeared that the name "Carwardine," composed of large letters, was placed upon the apparatus, and painted on the rudder or tail. The Court held that in its then state it came within the Act as being partly used for advertising purposes, being put up over the building, and visible against the sky; but they intimated that if the name of the owner, &c., were painted out the windmill itself would no longer be a "sky sign," and so it could remain.

In this case the Court said that what the Act meant to deal with was advertisements attached to any support over a house, or, in other words, put up over buildings in such a way as to have no other background than the sky. In the later case of Madame Tussaud's Exhibition (*Times*, November 11), this rule was applied with the result of beating the County Council. There the words "Madame Tussaud's," made of large wooden letters 3 ft. long, were fixed upon an open trellis-work of iron 35 ft. long, which was supported by iron posts, and braced back to the dome which surmounts the building. The sky could be seen through the letters on each side of the pavement, and the magistrates convicted on the ground that this was a sky sign put up before the Act was passed, and for which the license of the County Council should have been obtained. After much argument the Divisional Court held that the magistrate was wrong, and they set aside the conviction. The main ground of their judgment was that, though the trellis-work upon which the letters were placed was attached to the house, it was not "over" it. They held that the important words of the definition clause are: "Supported on or attached to any framework or other support wholly or in part over any house, building, or structure." But the Judges cautiously added that of course every case of this kind must depend upon its own facts and circumstances. **FRED. WETHERFIELD, Solicitor.**

1, Gresham Buildings, Guildhall, E.C.

NOTE.—All questions for reply in this column must be headed "BUILDING NEWS," and must reach my offices, as above, by Tuesday morning to insure answer same week.

X. Y. Z.—STABLES.—WALL.—I should say that the wall belonged to A upon the facts stated, and so that he could build upon it. But the point may be affected by the deeds of the property and the sale of adjoining premises to B. The wall would seem to have become a party-wall by being "used" as such.

G. T.—CHURCH.—ALTERATIONS.—Probably the rector would be legally entitled to order the alterations stated, especially if done with the consent of the churchwardens, who ought to be consulted upon such extensive work. Strictly speaking, structural changes cannot be properly made without faculties from the bishop for that purpose.

LEGAL INTELLIGENCE.

AN ARCHITECT'S CLAIM FOR FEES.—In the case of Swash v. Remy and Gilmore, heard at the last sitting of Newport County Court, and briefly noticed in our last issue, p. 725, we have received a fuller report out from a local newspaper, from which we gather that among the witnesses called by the plaintiff were Mr. G. Thomas, M.S.A., F.S.I., of the firm of Seward and Thomas, of Cardiff, who considered Mr. Swash had acted in a reasonable and proper manner in giving a certificate of final completion; Mr. Pickwell, architect and engineer, in whose opinion Mr. Swash had not been guilty of any professional negligence in passing these

houses; and Mr. J. D. Whittaker, surveyor, also gave evidence as to his belief that the houses were erected in accordance with the plans and specifications, and that Mr. Swash was not guilty of professional negligence. Other witnesses for plaintiff were Mr. Henry Carr and Mr. Richards, builders; and Mr. John Linton, president of the Builders' Association.

IN RE F. T. PITWOOD.—At the Stonehouse Bankruptcy Court, on Nov. 16, a solicitor applied for the discharge of Frank T. Pitwood, of Plympton St. Mary, builder. He said that the debtor started as a working mason and jobbing builder. In 1889 he commenced building two houses at Plympton, on which he expended £1,900, of which sum he borrowed £1,630. The Official Receiver said the total liabilities amounted to £2,627, which included £300 outside the mortgages. A dividend of 2s. 3d. in the pound had been paid on £271. Debtor continued trading for sixteen months after he knew the property would not realise the money advanced on mortgage. The whole furniture had been claimed by the debtor's wife, a laundress. The debtor was able to live now in far more comfortable circumstances than his creditors, and they felt that he had means somewhere which they could not trace. Counsel for creditors also opposed the application, and asked that debtor should not be granted his discharge until he had paid his creditors a composition of 10s. in the pound. His Honour, Judge Edge, made an order on the debtor to pay 5s. in the pound, or his discharge would be suspended for three years.

WHO IS THE BUILDING OWNER OF A CLUB?—**WINBURN V. NORRIS.**—The plaintiff, Mr. William Winburn, a builder, of Croydon, sued Mr. Arthur James Norris, of The Waldrons, Croydon, in the Queen's Bench Division, on Tuesday, to recover £230, the balance of a building account. The building operations were executed in the year 1888, at the South Croydon Conservative Working Men's Club, the premises of an old brewery being converted into a club-house. It was said, on behalf of the plaintiff, that the defendant, who was the treasurer of the club, was also the owner of these premises, and that he gave all the orders. The defence was a denial of personal liability by the defendant, and an allegation that the works were executed upon the credit of the club, of the committee of which plaintiff was himself a member. The defendant, it was said, merely found the money to acquire the premises for the sake of the club. During the plaintiff's cross-examination as to the minutes of the club, &c., the jury stopped the case, as it appeared from his own books that he merely regarded the defendant as the treasurer of the club, and verdict and judgment were entered for the defendant.

WATER SUPPLY AND SANITARY MATTERS.

RIPON.—Mr. Theo. S. MacCallum, A.M.Inst.C.E., Manchester, has made for the Ripon Corporation a preliminary report on the drainage and sewage disposal of the city. The object is to purify the sewage before it enters the river Ure, in order to comply with the requirements of the Local Government Board and of the County Council. Intercepting sewers are to be constructed, and the scheme will form a basis of further extensions. The works are intended to provide for a population of 10,000.

SHEFFIELD.—The Sheffield Corporation, like many others, has for many years past been troubled as to the disposal of its nightsoil. The privy system, with its usual accompaniments, and some special to the locality, flourishes in full vigour. Probably 50,000 houses have privies, and nearly 45,000 of these use them in common, four, six, eight, or more houses joining at two, three, or four closets. Some considerable time ago a committee reported in favour of the adoption of a system of water carriage, and the council towards the latter end of 1890 instructed its health committee to consider and report upon the means to be devised to carry out such a system for the town, more particularly with reference to the poorer classes of property in densely populated districts. The committee deputed a sub-committee to make the necessary inquiries, and to report. The sub-committee, after a full consideration of various forms of apparatus and methods of applying the water carriage system cheaply, yet efficiently, came to the conclusion that the only practical scheme for successfully carrying out the system in Sheffield must be one based upon the principle of the trough closet. Having decided that closets should be adopted, which, although separated from each other so as to insure perfect privacy, were yet independent of the occupier so far as their cleanliness was concerned, and were destitute of any apparatus that could be broken (all of which advantages are offered by trough closets), the question came to be, whether in such trough closets a reliable and suitable kind of water closet had been found, and if so, which of the many trough closets offered to the public by various firms ought to be recommended for adoption by the corporation. Leading firms were com-

municated with, and asked to place apparatus at the disposal of the corporation for testing purposes, and several firms complied with this request. Mr. G. Alsing, A.M.I.C.E., constructor of sewage works to the Bradford and Sheffield Corporations, and now engaged on a similar work for Glasgow, was, as engineering adviser, conjoined with the medical officer of health to carry out the trials. These gentlemen, in due course, made their report, which has recently been presented to the council. The report sets forth that the observations were instituted in order to find out, if possible, which was the best and most reliable automatic flushing trough closet under all conditions, and that the inquiry embraced three branches: (1) The supply of water to the flush tanks; (2) the flush tank itself; (3) the trough. The reporters state that under the first head there was at the outset considerable difficulty in getting a continuous feed at a slow rate through such taps as were then at the disposal of the committee, but that after communication with the various firms who had supplied apparatus, two were obtained which, under conditions which were devised, could, in the opinion of the reporters, "confidently be relied on, under ordinary circumstances, to run continuously and with little variation for a lengthened period without supervision." Under the second head the report states that in testing the flush tanks, certain special points had to be kept in view: (1) Absolute certainty of automatic action; (2) liability to run to waste without a flush taking place; (3) simplicity and stability of structure; (4) possibility of their being disabled willfully or passively by dirt or constant use. After detailing the behaviour of the various forms of apparatus, and pointing out the danger of all air-holes and small pipes in connection with flush tanks, which, if stopped by what the report calls "the omnipresent dirt," prevented the tanks from acting, "whether supplied with full pressure directly from the main or with only a small feed at low pressure. Instead of now flushing automatically, they simply ran to waste and refused to siphon," the reporters came to the following conclusion:—"From these experiments it will be seen that the only cistern which came absolutely scathless out of the several tests to which they were subjected was that of the Water Carriage Engineering Company, which never failed to flush under any conditions, and which, moreover, is from its construction extremely unlikely to get out of order, or admit of its being easily tampered with. We are, therefore, of opinion that of all the cisterns which we have subjected to observation, this one is the most reliable in every way, and that, under all ordinary conditions it can be depended on to act automatically and with regularity." Under the third head three points were judged to be the essentials of a satisfactory trough, viz.: (1) General suitability for forming separate closets; (2) stability and simplicity of structure; (3) cleanliness. The reporters state: "The form of trough which undoubtedly seems to us to be most favourable to a good flush is a triangular one, as exemplified in the two examples of the Water Carriage Engineering Company. By adopting this form, a minimum amount of water reaches a maximum amount of surface; or, in other words, with the same volume of water as in the other forms, less surface liable to be soiled remains unaffected by the flush." The council unanimously adopted the report, and has instructed the committee to draw up conditions under which the conversion of the present privies can be vigorously proceeded with.

CHIPS.

At a general meeting of the Institute of Painters in Oil Colours, held on Wednesday evening, Messrs. Frank Brangwyn, Alexander Mann, and J. A. Lomax were elected members.

A member of a vestry in Westminster, named William Smith, was prosecuted by his vestry, at the local police-court, on Wednesday, for delaying to carry out necessary sanitary works upon houses belonging to him in Marham-street. Ultimately further time was allowed for the works to be completed. Upon other summonses against the same defendant, orders were made for the repairs to be executed forthwith.

The Crediton improvement commissioners discussed, on Monday, a claim from the surveyor for fifteen guineas for extra work. A proposal to pay him this was lost, as was also an amendment to pay him ten guineas for it. The surveyor intimated that he should have to take other proceedings.

A lych-gate of oak, with Broseley tiles, and new wall capped by iron railings, have just been erected at Merton Churchyard, Devon. The work was executed by Mr. H. Read, of Exeter.

A temporary smallpox hospital has been built for the Otley local board. The building is of wood, and covers an area of 60ft. by 70ft. Mr. Trow, surveyor to the Otley local board, prepared the plans, and the work was carried out by Mr. Patrick, joiner, Otley.

Our Office Table.

THE London County Council will apply to Parliament in the ensuing session for leave to introduce a Bill "to impose, or provide for, or authorise the imposition of a new rate or charge on lands and property within the County of London or the owners thereof, the proceeds of which shall be applied in aid of the cost of improvements and works of public utility effected" by the Council. The Bill may also "provide for the manner in which such rate or charge shall be collected in respect of vacant lands or unoccupied or public buildings." Application will also be made to Parliament by the Council for leave to introduce Bills under the following titles: "London Improvements," "London Open Spaces," "London Streets (Removal of Gates, Bars, &c.)," and "London County Council (General Powers)."

A PUBLIC improvement has just been completed at Manchester by removing the heavy railings on the north and west sides of St. Ann's Church, thus converting a narrow passage at the west end of the church into a broad thoroughfare, and increasing the width of another street. The works have been carried out by the Manchester Corporation, who will pay the trustees a rent of £100 in perpetuity. St. Ann's Church is, with the exception of the cathedral, the oldest one in Manchester, having been built from Wren's plans, and consecrated by Sir William Dawes, Bishop of Chester, on July 12, 1712. It was partially restored in 1890, at a cost of £1,000, but more important alterations have yet to be effected, as soon as the funds, amounting to about £1,500, can be raised. These further works include new side staircases to the gallery; the opening out of the west entrance, making it, as originally, the principal entrance to the church; the removal of the organ from the west to the north gallery; and the filling of the windows throughout with new mullioned and transomed frames and glazing. The pews and wainscot panelling and gallery front on the south side of the nave are also to be restored, cleaned, and adapted to modern requirements, to harmonise with those already treated on the north side.

THE directors of the Nottingham Trade Protection Society have forwarded to the Lord Chancellor a memorial, calling attention to the state of the law with regard to rights of light. They are convinced that the interests of traders very frequently suffer in the centre of large towns, when, upon requiring to rebuild and modernise their places of business, they find their plans thwarted by reason of rights of light, which rights are frequently exercised in a manner that is not for the good of the community. Very often, as they pertinently remark, a fictitious value is put upon windows and openings which are of small value, and buildings have to be dwarfed and cramped for fear of damages. Moreover, great uncertainty prevails, as the owner rebuilding has often no means of ascertaining what will satisfy his neighbour, should he refuse to declare himself, until an application is made to restrain, or an action is brought for compensation, whereupon professional witnesses on both sides are forthcoming to seek to minimise or increase the value of damage done. In order to prevent this uncertainty, the memorialists suggest that it is desirable a local authority in each town should be constituted, to whom either party might apply, and who should have authority on the spot to examine the old building if standing, or the new one if erected, and who should be authorised to decide the size of the proposed openings, the height of proposed buildings, or otherwise. They conclude by asking Lord Herschell to give attention to the matter with a view to the bringing into Parliament a Bill, so as to secure the objects indicated.

THE Stafford board of guardians discussed at their last meeting the charges made by Mr. Wormal, architect, for preparing two sets of plans for the new workhouse infirmary now in course of erection under his superintendence, Mr. Espley, of Stafford, having taken the contract at £3,900. Mr. Wormal's bills amounted to £310, being £115 for the plans rejected by the Local Government Board, and which included besides the infirmary a chapel and lodge, and £195, being 5 per cent. on the works actually in progress. Several members expressed an opinion that £115 was a large sum to pay "for nothing."

—i.e., for an architect's time and labour for plans not passed by the higher authority, but the clerk said no special arrangement was made with the architect when instructions were given him. Ultimately a resolution was passed offering Mr. Wormal £250 in settlement of all charges, in effect equivalent to docking 50 per cent. from his bill for the rejected plans.

Mr. J. Lewis, of 5, Great Winchester-street, London, E.C., has patented an invention relating to the couplings which in lightning conductors serve to connect the top rod to the copper tape, and it has for its object to provide a device by means of which bad contact, which is liable with couplings now in use owing to the two parts which constitute the coupling not fitting properly and to negligence on the part of the workman or otherwise, may be avoided. The coupling, instead of being made in two pieces, as heretofore, is made in a single piece (approximately of link or stirrup form), and having sockets at its upper and lower parts, the former being cylindrical and screw-threaded for attachment of the top rod, while the latter is of flattened and of dovetail or wedge shape for retaining the tape, which is secured to the coupling by passing it through the socket, and out laterally, and then doubling the end of the tape on itself, so that when the tape is drawn back its end is jammed in the socket, and it is effectually prevented from becoming detached; the strain on the tape assists materially in maintaining good contact. The idea is a good one, and should be generally adopted.

The American Institute of Architects at the twenty-sixth annual convention, recently held at Chicago, under the presidency of Mr. E. H. Kendall, decided to formally petition the U.S. Treasury Department that the name of William Frazier, which is now on the Treasury in Wall-street, New York, as an architect, be expunged, and that the name of William Ross, who was the real architect, be substituted, as it has been discovered that Frazier was only superintendent, while Ross had designed the building. It was also recommended that every architect should cut his name on his own building—a plan that has been adopted, it will be recollected, by a few architects practising in the City of London by no means in the first rank of our professional men.

The Union Tare Indicator Co., of Adelaide-street, Halifax, draw our attention to their patent tare indicator for indicating the tare weights of animals and vehicles. Should a change of animal take place, the indicated tare weight can be altered by simply removing the lock and bar from the indicator, and turning the wheel or wheels in any direction so as to produce the figures required. After this operation, which only occupies a few minutes, the lock and bar are replaced in their original positions.

The Frascati Restaurant, 32, Oxford-street, W., has, under new management, recently reorganised its resources—which probably surpass those of nine out of ten similar establishments in London—to good purpose. The restaurant and Winter Garden is situated on the northern side of Oxford-street about fifty yards west of Tottenham Court-road, having a frontage of 110ft., an elevation of five stories, three entrances in Oxford-street and one in Hanway-street, to which the buildings extend in the rear. The front building contains the buffet, restaurant, ladies' toilet rooms, grand banqueting hall, and ballroom (capable of dining 150 guests), Masonic temple, reception and billiard rooms, the latter having five English and three French tables. The central buildings are occupied by the Winter Garden (in which is placed the orchestra and reading-room), illuminated by nearly 1,000 incandescent lamps, and is approached from all entrances. The café restaurant occupies the ground floor, while the balcony is reserved for table d'hôte and French dinners. In addition to the above, there are various ante-rooms, gentlemen's lavatories, offices, stores, wine-cellars, kitchens, and an electrical installation comprising over 2,000 lights. A capital programme of music is rendered nightly in the Winter Garden from 6 till 10.

At Tuesday's meeting of the Coventry Corporation the City Surveyor reported that during the year plans had been sanctioned for the erection of 132 dwelling-houses, being a decrease of no less than 432 on the previous year, and 36 on the year 1890.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Society of Arts. "The Generation of Light from Coal Gas," Cantor Lecture No. II., by Prof. Vivian Lewes. 8 p.m.
Society of Engineers. "The Shortlands and Nunhead Railway," by A. G. Drury. 7.30 p.m.
TUESDAY.—Society of Architects. "Levelling and Counting as Applied to Architecture and Landscape Gardening," by G. W. Usill, R.M.Inst.C.E. 8 p.m.
Institution of Civil Engineers. "The Manufacture of Small Arms," by J. Rigby, of Enfield. 8 p.m.
WEDNESDAY.—Society of Arts. "The Copper Resources of the United States," by Jas. Douglas. 8 p.m.
FRIDAY.—Architectural Association. "Daylight in the Dwelling-house," by John Brett, A.R.A. 7.30 p.m.

The Architectural Association.—December 2. The Third Ordinary General Meeting at 7.30 p.m. Paper by John Brett, Esq., A.R.A., on "Daylight in the Dwelling-house."
ERNEST S. GALE
F. T. W. GOLDSMITH } Hon. Secs.

Trade News.

WAGES MOVEMENTS.

THE WAR OFFICE AND WAGES IN THE BUILDING TRADES.—A deputation of workmen and trade-unionists, consisting of Mr. G. Dew (General Secretary of London Building Trades Committee and Amalgamated Carpenters and Joiners), Mr. J. Rogers (Amalgamated Painters and Decorators), Mr. P. Weighill (Stonemasons), Mr. W. Gibbs (Operative Bricklayers' Society), Mr. W. Brooks (Lathrenders), and Mr. J. Verdon (Secretary London Building Trades Federation), on Saturday attended at the War Office respecting the alteration of rules which has taken place in the building trades. The deputation was received by the Assistant Secretary. Mr. Dew explained the new arrangements and the minimum rate of wages as agreed to in June last by the Master Builders' Association and the London Building Trades Federation, as representing the workmen, and asked the Government to adopt the same, or put a clause in all contracts compelling all contractors to pay the recognised trade-union rate of wages, or a clause whereby the current minimum rate of wages would be paid. In answer to Mr. Brooks, the Assistant Secretary said that, in consequence of the information he had supplied respecting the lathrenders, the War Office sent an inspector to Aldershot to make inquiries respecting the using of foreign-made laths. That official confirmed Mr. Brooks's complaint, and the War Office had now decided that only English hand-made laths were in future to be used in Government work. The Assistant Secretary said the matters brought forward should be carefully considered. The War Office was always willing to receive deputations from practical workmen with respect to the work being carried out by the Government.

CROYDON.—A strike has occurred in the building trade in this borough through the refusal of the master builders of that district to recognise the London radius as defined by the conference of workmen and the Master Builders' Association in May last, and which came into operation on November 7.

CHIPS.

The Barrow Island School is being warmed and ventilated by means of Shorland's patent Manchester grates, the same being supplied by Mr. E. H. Shorland, of Manchester.

An adjudication in bankruptcy has been made in the case of Joseph Chinchin, of East Cowes, I.W., builder and contractor, and surveyor to the East Cowes local board of health.

In the case of John Thomas Farley, of Truro, builder, the discharge from bankruptcy has been suspended by the Court for four years, ending October 6, 1896.

An inquest was opened on Wednesday week at Cullyhanna, near Crossmaglen, Newry, on a stone-mason named Patrick Bennett, aged 50, who was accidentally killed whilst working at Cullyhanna Catholic Church, now in process of erection. The deceased and a labourer named James Robb were removing the centres which supported the chancel arch during construction, when the arch collapsed. Robb escaped with a shock, but Bennett was killed on the spot. Father Kerley, P.P., and Mr. Wynne Dundalk, builder of the church, were present at the inquiry. The inquest was adjourned for the attendance of the architect of the church, Mr. Haigue, of Dublin.

Holloway's Pills are specially adapted for the young and delicate; their gentle and purifying action ranks them above all other medicines. In indigestion, nervous affections, gout, and rheumatism, these Pills have achieved for themselves universal fame. They expel all impurities from the blood, and thus restore cheerfulness and vigour.

THE BUILDING NEWS AND ENGINEERING JOURNAL.

VOL. LXIII.—No. 1978.

FRIDAY, DECEMBER 2, 1892.

THE NEW WORKS DEPARTMENT OF THE LONDON COUNTY COUNCIL.

LONDON has been given, in the announcement, referred to by us in our issue of last week, of the new Works Department by the London County Council, one of the most important pieces of building news to digest that has come before the public for many years.

After deciding to become their own builders, it was, as we have already pointed out, the one and only course open in order to make the scheme at all workable. Experience, and experience alone, will enable the public to decide whether or not the principle of turning a municipal body into an employer of labour on such a large scale as the carrying out of the works of the Council will compel is a wise one. The Press generally have considered the question of such vast importance to the ratepayers of London, that they have devoted much space in arraying, according to the various shades of politics they represent, the advantages and disadvantages that will accrue from the adoption of the resolution of the General Purposes Committee by the Council. We cannot sympathise in any way with mixing up politics and questions affecting the local government of our Metropolis. If the creation of the Works Department is but a bait to catch the labour vote, as has been suggested, we most strongly deprecate the action of the Council. If, however, a genuine desire to benefit the ratepayers as a whole, and not as a class, influenced the Council, then we must heartily wish the venture every success, especially as we feel this motive was uppermost in the minds of the majority of the members.

It is well, however, to weigh this question quietly, with an impartial mind, and to review the opinions that have been expressed by both sides, before arriving at any judgment of the wisdom of the great changes it involves, changes which we must venture to think the Council themselves have not yet foreseen. Little time was allowed to elapse from the day when it was resolved to build the artisans' dwellings at Blackwall without a contractor, and the day when the General Purposes Committee presented their report with the whole scheme, evidently in accordance with their views, cut and dry, for carrying out the Council's work in the future; but it does not require a very experienced eye to find out that the arrangements proposed are far from complete. Take, for instance, the organisation of the staff: we are not alone in considering that the salary of £700 a year for the "manager of works and stores" is deplorably insufficient, and will not enable the Council to secure a man of sufficient *locus standi* to fill the post to the credit of the Council and the benefit of the ratepayers. Whatever the members themselves may think, it is this official who will make, or mar, the whole scheme. Doubtless they flatter themselves that the new "Works and Stores Committee" will be the hand that will hold the whip and the reins; but how, we ask, can a body of men who have had no experience whatever in the building trade, who have but partial leisure and their own business to carry on—how can these men, with no technical knowledge, and varying opinions, and perhaps fads, be expected to conduct a huge contractor's business with the same exactness, the same completeness, and with the same advantages, as a man who has been trained from boyhood to

every branch of the vastly complicated calling of a builder? The London County Council will fail most egregiously in this undertaking if they do not place the chief officer of the new department in exactly the same relation with their architects and engineers as they would an outside contractor.

The Council, it must be remembered, not only employ their own architect and engineer, but other professional advisers are from time to time called in. For example, Sir Benjamin Baker was consulted in reference to the Blackwall Tunnel; the Municipal Lodging-house, in Drury-lane, is in the hands of architects not on the staff of the Council; and Claybury Asylum is being carried out by Mr. George T. Hine. In the future, not only the architects and engineers on the staff of the Council, but also architects and engineers in private practice, must come in contact with this new official. Supposing, inadvertently or otherwise, bad or inferior material were introduced into a building, who is to condemn this material? Is the architect or engineer, whether on the staff or not, to report against a brother officer or against his masters, the committee? Is the architect to lose all control over this substitute for a contractor, and is he or the engineer only to "prepare plans," and not be responsible in any way for the carrying of them out? If so, the scheme will not be a success; the architect and engineer should certainly retain the same power of supervising the work as under any contract with a builder.

Again, the success of the scheme greatly depends upon what kind of control the committee maintain over their paid officers. It will be impossible for a body, constituted as this committee must be, to supervise every detail; but unless they do, the whole responsibility must rest with the staff. A contemporary argues that a committee of a changing elective body, composed of persons who, in regard to such business as that of building or draining works, must necessarily be amateurs, is not likely to show efficiency in the control of large, costly, and complicated undertakings. If it leaves everything to its chief officer and its departmental staff, it will create a "dangerously powerful bureaucracy which may not always be incorrupt, and which is almost certain to become obstructive." If it meddles with details, it will reduce the departmental officials to abject insignificance, and will meet with the usual success of amateurs. We are also reminded that the downfall of the Metropolitan Board of Works was caused, not by the corruption of the members of the Board, but by the corruption of its officials, and that there is hardly any line of business where corruption is more easy than in the building trade. "The Council," it has been said, "in its laudable desire for economy, has fixed the rates of payment on a very moderate scale, thus making the temptation all the greater."

Now look for a moment what is required of the chief officer. In return for £700 a year, he shall be responsible under the Works Committee for advising as to the purchase of stores, plant, and material; the execution of all works carried out by the Works Committee on behalf of the Council; the employment and supervision of all officers and workmen in his department or employed on works; the regulation and direction of all store-yards, depots, and workshops belonging to the Council.

We venture to think the Council will meet with the same difficulties they did when they wanted a "chief" for the Parks Department. As they could not get a man who was fit to undertake the work for the money they offered, they did the best thing they could under the circumstances, by raising one of their own officers to the position. But in this case they cannot fill the post from their own ranks; they must go to the outside world,

and doubtless will find hundreds willing to undertake the "job," but whether any of them will be more fit for a "job" than the post must be merely a matter of surmise. The *Times* forbears from conjecturing whether a person endowed with these varied aptitudes is likely to be secured by the Council at the reduced salary of £700, on which the majority insisted, for the committee were gracious enough to suggest £1,000 a year.

It would be impossible to create an office more open to temptation, or, on the other hand, more open to false imputations, than this one of the Manager of Works and Stores. The Council should, therefore, offer a "fair wage," and not begin their new venture by brain-sweating, which they were warned against some little while ago.

We pity this officer, who, while he is endowed with "a thorough experience of the purchase of material and plant, and the carrying out of large works under some well-known contractor," has to submit to the caprices of a changing body like a committee; for what may please this Council, may not please a Council of three or six years hence. He will have to be a man who, while knowing everything in the building trade, must have no mind of his own.

We strongly urge upon the Council the desirability of obtaining the very best man that can be got, and to pay him well for his work. This, we feel sure, would be an act of wise economy.

Looking deeper into the report, it will be found that it is not the intention of the Council to invest their new officer with unlimited power; on the contrary, the intention is that the power shall be vested in the "Works and Stores Committee," which is to carry into execution all works which the Council resolves to execute without the intervention of a contractor, and control the staff exclusively employed in connection with the works of construction and repair undertaken by them, and is to consider and report to the Council as to the provision of store-yards and workshops necessary for carrying out the works committed to them, and to control all store-yards, workshops, and store depots of the Council, and carry out the regulations of the Council as to store accounts, tenders for stores, and the ordering, issue, and condemnation of stores. In addition to this, the further duties of this committee are that, when the Council shall have resolved to execute any works without the intervention of a contractor, and shall have passed the necessary estimate of the cost of such works, the committee shall have power to contract, on behalf of the Council, for the supply of plant and material, provided that the amount of the contract does not exceed £500, and provided that no contract be entered into by the committee which shall cause the above estimate to be exceeded without the special authority of the Council, and provided also that no contract involving an expenditure of more than £100 shall be entered into except after public advertisement. On the motion of Mr. Westacott it was added that, on the completion of the works referred to the committee, they shall forthwith report to the Council that such works are completed, with particulars of the estimated and actual cost thereof. This wise provision was not, it must be observed, embodied in the General Purposes Committee's recommendation to the Council. Further, separate accounts of liabilities entered into in connection with each work have to be kept, and information of every liability entered into reported upon to the comptroller of the Council. The committee have to undertake the preparation of the schedules and the consideration of the tenders for all goods supplied to the Council, and consider all questions as to contracts for general repairs.

This committee is to consist of 15 members, 12 elected from other committees, one from

remnants of verdure-clad houses. No. 12 represents an "Old Parsonage Farm, Eastbourne," a greystone wall covered by thick clematis foliage, save an old Gothic doorway, at which a woman with child in her arms stands, every detail being rendered with that conscientious fidelity to nature and that instinctive love of the beauties of rural life which always entitle this lady's work to rank as poetical. In this and an "Isle of Wight Cottage" (177) we see more than a close and literal transcript; the work is sympathetic, as if the painter wanted to make us feel the true beauty and charm of the scene. In a stronger and more masculine mode of expression, Robert W. Allan paints his grand "Summer Day in the Highlands" (15), a broad valley through which a silvery rivulet meanders and sparkles, the hillsides wild and treeless, with a grey mountain in the distance. The warm brown and greys of the landscape are forcibly painted. Mr. Allan's other works are a landscape in "Sussex" (79), solidly handled, with much depth of tone; "Rothenburg, Bavaria" (96), vigorous and dark masses of foreground, and reflected light in the water; and a strongly-coloured view of "Kirkwall Harbour" (182). Several pleasing subjects are sent by Tom Lloyd—perhaps a little tame sometimes. His "Sunrise on the Marsh," cattle crossing a bridge (16), cleverly depicts the rising mist over the meadow. "A Breezy Haytime" (39) is a companion subject; we have the river bordering the hayfield, and the figures are pleasingly drawn. Another sunny landscape is 86, a cornfield, and a fourth is "The Close of a Midsummer Day" (167); the rising mist and reflection in river are feelingly painted, but we like his "Tea in the Garden" (21), a smaller study of figures and flowering plants, displaying much delicacy of handling and colour. Thomas M. Rooke is another large contributor. His old houses, Dinan (22), "Knitting Women, Vitre" (41), "Castle of Fourgères" (268), and "Mont St. Michel" (279) are picturesque subjects drawn with the artist's usual sharpness, but lacking repose in some cases. We admire Chas. Gregory's "Caudebec," a street scene, and his springlike "May Morning" (289). One of the best works of Albert Goodwin is "Canterbury," a bird's-eye view of the city; another is his "Oxford from Radcliffe," a delicately and well-drawn view representing the quadrangle and the city under a veil of evening mist. R. Thorne Waite is prolific in landscape, haymaking, cornfields, and marshes are his subjects. Many of these exhibit breadth and artistic grace. "Carting Corn" is a large drawing of cornfield by the sea, a loaded waggon being full of the ripened grain. The horses and labourers are vigorous and full of life. "Romney Marsh" (118) is broad, and the light and colour admirable. Various other sketches are exhibited on the screen, all full of true poetical feeling, and admirable in grouping and colour. Miss Clara Montalba charms by her beautifully soft melodies of pearly greys. Her Swedish sketches (29) and coast scenes (47), "Early Morning" (162), are most captivating colour studies. W. Eyre Walker (74) has a fine study of sycamores and some other tree studies. William Collingwood contributes a splendid mountain peak tipped by rosy light, "Monte Rosa" (52), and other mountain studies of exquisite colour. Walter Crane sends a clever sketch for a decorative subject, "Neptune's Horses" (38).

Mr. Arthur H. Marsh (85) sends by far the best figure subject, "The Messenger," a picture full of pathos, and of masterly drawing. It represents a cottage home by the sea. A young fisherman is knocking at the door, while a number of villagers, women and men, are standing anxiously in front awaiting the sad message which the young fisherman has brought to the hapless

inmates. The expressions of sympathy and expectation are visible in the women's faces, and the figure of an old fisherman keeping back the too-eager and gossiping friends is excellent. This work is given a place in the centre of gallery, and its merits as a composition entitle it to honour. In the corner, E. R. Hughes's "The Poet Gringoire" (64) has also much of the pathetic in the seated figure of the handsome young man who has two children under his cloak. On the other end of gallery is a choice collection of designs of imaginative and Scriptural subjects. The principal design is "Gloria in Excelsis" (249), illustrating that noble ancient hymn of the Church, which is supposed to belong to the first century. The painter represents here in pre-Raphaelite minuteness the vision of the heavenly hosts, including the Saviour, with the Bethlehem shepherds rising from their slumbers below. The figures in the vision are not all obvious, and may be open to criticism, yet there is something grand about the conception from a decorative point of view. "The Impetuous Neighbour" (250) is more representative of Mr. Holman Hunt's genius; his interesting portraits in silver point of "Christ Before Pilate" and "The Hidden Treasure" (245) are valuable examples. The President, Sir John Gilbert, R.A., has only one subject (160), a fine "Study of Trees" in a forest, the trunks being vigorously painted in Sir John's best manner. The study has an oil-like depth of tone. E. Burne Jones, A.R.A., has a charming study of a head for "The Golden Stairs" in brown crayon, on the screen. Ernest A. Waterhouse sends two or three subjects. "Over the Sand-hills," with its sunlit crest of hills and sheep, is the best. A corner picture of much power in drawing and colour, is R. Beavis's No. 104—

"Green Sussex fading into blue
With one grey glimpse of sea."

—a fine rendering of Tennyson's verse; the oxen-drawn plough is a strong piece of drawing and colour. We may also notice J. Henry Henshall's "No Compromise," Miss E. Martineau's "Sketch of Hastings" (110), S. P. Jackson's coast scenes (111), A. Hopkins's "Sea Study" (120), Sir Oswald Brierley's fine studies of marine subject and seascapes (209), and his fine Venetian subject (282). Birket Foster is still full of that sense of natural beauty and finished execution which delighted a past generation. His "Bridge over the Cluny" (147), "Water Mill" (154), "On Hambleton Common" (185), "Near Bonchurch" (303), are delightful in drawing and colour. George A. Fripp sends several very beautiful studies of coasts. His "Coast of Sark" (157) is a delightful rendering of stratification of rock and of luminous colour. Mr. Alfred W. Fripp has one fine drawing of the Lion Rock, Dorset (164), and Charles E. Fripp several sketches and drawings of foreign subjects of interest. H. G. Glindoni has a large figure subject entitled "Billeted" (215), an interior of tavern in which a number of soldiers and drummers are seated, drinking and playing dice, a scarlet-coated captain good-humouredly chucking under the chin the daughter of the host, who looks indignant at the familiarity. E. K. Johnson's "Birthday Ode" is a cleverly-drawn garden scene. We see also some good work by J. W. North (170); Edward F. Brewtnall; Robert Little (143), a graceful figure-study; some characteristic sketches by William Callow, "Barnard Castle" (121); and a very clever study, "Domestic Troubles," by John Burr; and others by R. Thorne Waite, and pen-and-ink sketches by Du Maurier on the screens.

THE SOCIETY OF ARCHITECTS.

THE second ordinary meeting for the present session of the Society of Architects was held on Tuesday evening at St. James's Hall, Picca-

dilly, when there was a large attendance of members and lady visitors. Mr. William Allport, F.S.I., member of council, occupied the chair. Three nominations for membership were announced, and the following eleven new members were elected:—Frank Eumley, Johannesburg and Pretoria, S.A.R.; William Cecil Jackson, Skellington, Grantham; Jowett Kendall, Calverley-chambers, Victoria-square, Leeds; Edwin Fewster Waugh Liddle, 24, Collingwood-street, Newcastle-on-Tyne; Arthur Newsome, Queen's-square, Middlesbrough; Henry Charles Portsmouth, Castle-buildings, Swansea; Ernest Ryley, Imperial-chambers, Albert-street, Derby; Lewis Frederick Shove, 49, Apsley-road, Clifton, Bristol; Percy Bertram Stradwick, The Corner, High-street, Bromley, Kent; Joseph Swarbrick, A.M.Inst.C.E., 44, Brazenose-street, Manchester; and Thomas George Williams, 3, Cable-street, Liverpool.

The Chairman said he regretted to state that Mr. G. W. Usill had been unable to prepare his promised paper on "Architecture and Landscape Gardening" owing to ill-health. Their energetic secretary, Mr. G. A. T. Middleton, had, however, been good enough to come forward at short notice, and would give an illustrated lecture on

SOME TEMPLES IN GREECE AND SICILY.

MR. MIDDLETON said he thought we were rather apt to overlook the claims to our attention of the many temples erected outside Greece, and he had therefore thought that an attempt to compare the Classic work in Greece itself with that executed in one of the Greek colonies, could hardly fail to be of interest to many, even though the materials for comparison had been hastily compiled. He proposed, therefore, to show that evening, by the oxy-hydrogen light, between 20 and 30 views of temples in Athens and Sicily, reproduced from photographs taken this summer by Mr. Soames, a London architect, and kindly placed at his disposal. Of the Doric temples in Greece, the lecturer continued, the best known are undoubtedly the Theseum and the Parthenon. The latter has been exhaustively described already before this Society, in a paper read by Mr. Stanley Peach, on April 13, 1886, and then illustrated by restored plan and side elevation of this most refined and dignified of Doric edifices. It stands alone as an octastylar Doric temple, and this fact, neglecting its many wonderful refinements, gives it a breadth which is to some extent lacking in the more usual hexastylar form. Even in its ruined state—for its one-time use as a powder-magazine had a somewhat damaging effect upon it—it still remains as a wonderful monument of genius, a fit crown to the height of the Acropolis at Athens. Its beautifully delicate, graceful, yet masculine sculpture, has been renowned through all ages. The Theseum, standing in the plain close by, and finished as early as B.C. 465, is, upon the contrary, a typical and not an exceptional example, and serves the better as a type that it still remains almost perfect. The proportions of its order are very similar to those of the Parthenon, but the rake of the pediment is considerably greater, and its sculpture, to judge from that in the British Museum, is bolder and less refined. If it be in Greece, however, that we find the most finished examples of this order, it is rather in the provinces that we find those of greatest interest. Athens was built only between two great wars, and the period of building extends therefore over a comparatively short space of time. In Sicily, on the contrary, there are noble examples of much earlier date, and although it is most difficult in many instances to state with any degree of precision when the temples were erected, there yet appears to be a regular succession of examples from the earliest Doric times—in the estimation of some as early as 800 B.C.—until the island was overrun by the Carthaginians in B.C. 407-408. This exceedingly early date is given to the temple at Solunto, and, without accepting this to the full, it is borne out to some extent by the sturdiness of its proportions, by the lower third of the column being unfluted, by the flutes when they occur being sixteen in number (found in some other Sicilian examples also, as at Paestum and Girgenti), and by the very much compressed echinus to the capital. Upon the other hand, there are enrichments, such as the leaf and dart, carved upon some of the mouldings, and the spacing of the columns is so widely apart that two triglyphs appear between each pair of shafts. The

Temple of Neptune at Paestum (or Poseidonia) is one of the best-known examples, for its shell remains almost intact, and it is mainly remarkable for its greatly projecting echinus, a feature which some authorities consider to be characteristic of provincial work, forgetting that such a widely different example as that at Solunto exists close by. The fact that, being a hexastylar temple, it has fourteen columns on each flank, is scarcely an eccentricity, seeing that various examples differ considerably in this respect. At Selinus there are the ruins of several great hexastylar temples, evidently destroyed by earthquake, for the columns of that by the seashore have fallen outwards in all four directions. The result of their destruction has been to bring the details within easy reach of inspection, and the great capitals, with flat and widely-projecting hyperbolic echinus, can readily be examined. The triglyphs, too, show an appreciation of the values of small refinements which is worth notice, in the wave form of the terminal stops to the sinkings; and the sculpture, ascribed to any date between 628 and 450 B.C., is worth comparing in its early vigour with that upon the Parthenon. At Lepanto, there remains the shell of an unfinished temple, having no cella, authorities differing so widely as to the time of its erection as to name the date of its relinquishment as either 580 or 609 B.C. Its heavy proportions (for the entablature is half as high as the columns) seem to bear out the contention for the earlier date; but the historical events would rather lead us to believe that the latter was the more likely. It will be noticed that there is no stylobate, its place being taken by a flat circular drum of stone at the base of each column, somewhat larger in diameter than the column itself. That the columns were not fluted was possibly due to the fact of the work being unfinished; but the evidence in support of the contention that flutes were commonly cut *in situ* is scarcely complete, and there is distinct proof that the contrary sometimes obtained. This is afforded by an unfinished capital intended for the Temple of Concord at Girgenti (Agrigentum), where the shallow sinkings for the flutes can be distinctly seen. The shell of this temple still exists, and the semi-circular arches in the side walls of the cella will be noticed with interest.

There are other temples at Girgenti, each of interest—that of Juno for its great massiveness, and that of Castor and Pollux for its many unusual points of detail. The stops to the flutes appear rather as festoons below the echinus, which latter is deep, and with comparatively little projection. The leaf and dart again appears carved upon the bed-moulding to the cornice, and the topmost member of the pediment cornice is the ogee in place of the usual oval, with a very small carved bead above it to divide it from its fillet—an exceedingly beautiful and rare combination. The Doric order was undoubtedly the favourite of the Greeks, and was employed by them, both at home and in their colonies, in all their more majestic buildings. It was to the Ionic, however, that they turned whenever they desired a gem of more than usual elegance; and it is well to bear in mind that at Athens, at least, the two orders were employed contemporaneously. It is there, too, that the two most perfect Ionic works are to be found—a third, the Temple on the Ilyssus in the plains, having existed also so recently as to be fully described in Stuart's book. Of the two existing examples, the earlier is that known as the Temple of Wingless Victory, existing in Stuart's time only in scattered fragments, since pieced together by Rosso Schuberl, and re-erected on its original site just without the Propylæa of the Acropolis. It is so beautiful, and so little known, that a few words of description may not be out of place. It is quite small, measuring but 28ft. by 17ft. externally, stands upon a stylobate of three steps, is tetrastylar and amphi-prostyler. The base consists of a narrow roll, a side shallow cavetto, and another deeper roll above, each member separated from the next by a fillet, and the upper roll richly fluted, and this base is carried round the cella, as well as being used to the columns. The columns themselves are of the usual Ionic form, and the volute of the capital drops far below the level of the fillet, which separates capital from column, being generally deep in character. Round the cella three plain off-sets lead to an abacus, similar to the very slight one over the capitals. Above, the architrave is in three stages, and this is surmounted

by a sculptured frieze, only part of which has been found, all superincumbent work being missing. The other Athenian example of an Ionic temple, the Erechtheum, is much better known. This triple temple was erected within the walls of the Acropolis, and is generally ascribed to so late a date as about 450 B.C., a former temple upon the same site having been destroyed a few years earlier. As the Parthenon has been generally considered to be the greatest example of Doric, so has the Erechtheum of the Ionic. It exhibits more variety of outline than, perhaps, any other Grecian building, with ample carved enrichment placed exactly where it would be most effective. No sculpture is more beautiful than that of the caryatid figures to the altar-porico; no carving is more exquisite than the honeysuckle ornament upon the frieze of the largest Ionic building, the Temple of Diana at Ephesus. The remains are fragmentary, and but recently discovered; but those which are in the British Museum are of wonderful beauty. The great Ionic capitals show how even this enriched order is capable of being treated so as to express majesty, and may be well compared with the rich Corinthian capital, destitute of volutes, from the same building, while the carver and the sculptor will find there many a model worthy of protracted study.

Mr. GEORGE BAINES proposed a vote of thanks to Mr. Middleton. This was seconded by Professor HENRY ADAMS, who observed that their versatile secretary had shown them that neither in Athens nor in Sicily could modern conditions of building operations have prevailed when these temples were erected. There was manifestly no working by piece, no penal clauses limiting the time for completion, and no clients desirous of obtaining a building for half its proper cost.

Mr. FREDERICK JOHNSON, formerly a judge in Jamaica, supported the vote of thanks, remarking that to those accustomed only to the modern reproductions of Greek art, such as was seen at St. Pancras Church, Euston-road, these photographic views came as a pleasant surprise, while the Society was to be congratulated on having a secretary who could without warning put the points before them in so clear and graphic a manner. The vote was heartily accorded, and duly acknowledged.

THE L.C.C. AND THE ALBERT PALACE.

THE future maintenance of the Albert Palace at Battersea as a free place of recreation is assured, the London County Council having agreed at their meeting on Tuesday to apply to Parliament for power to accept the palace provided the freehold of the building and grounds is handed over to them free of expense.

The matter came before the County Council in the form of a report from the General Purposes Committee, who submitted the conclusions at which they had arrived with reference to the acquisition of the palace and grounds as a place of recreation for the public. The Vestry of Battersea had passed a resolution agreeing to contribute the sum of £5,000 towards the purchase of the building on the following conditions:—(1) That the Council should contribute not less than £5,000, and should maintain the whole of the premises free of cost so far as the vestry was concerned; (2) that the amount necessary to complete the purchase and pay costs should be contributed by either public or private subscription. The committee had also been informed that, in addition to the £5,000 offered by the vestry, a most generous offer, first of £10,000, and afterwards of an additional £3,000, had been made by Mr. J. Passmore Edwards, the proprietor of the *Echo*, the *Weekly Times and Echo*, the *Building News*, and other journals, making altogether £18,000 towards the purchase-money. They had further been given to understand that, provided the Council would undertake to maintain the palace, efforts would be made to raise by public or private subscription the remainder of the sum required to complete the purchase, and to put the building into a fair state of repair. They thought such an opportunity of securing for the people of London a building like the Albert Palace should not be lost. Should the Council decide to accept the charge of the palace and grounds, they were of opinion that they could be more economically managed and maintained as part of Battersea Park. They had had a report on this basis from the architect of the Council, and his estimate was £4,700. For the information of the Council, they gave

the following particulars with regard to the palace. The cost of the building was, they understood, over £100,000, apart from the value of the site. Including Connaught Hall, it covered three acres of ground. The building was divided into two portions, one, on the north, of iron and glass after the manner of the Crystal Palace; the other, on the south, of brick and quarried stone. The organ in the palace was considered to be the largest and finest in England, and cost £5,000. There was also a large picture gallery specially built for the purpose. The committee recommended: "That, subject to the Albert Palace, together with the grounds attached thereto, being handed over to the Council free of expense and in good repair, the Council do apply to Parliament in the next Session for power to accept the gift, and to manage and maintain the palace and grounds as a place of recreation for the public."

Mr. John Burns, M.P., explained that the palace cost about £100,000, and was within a few feet of Battersea Park, with which it could be connected by an underground passage. Seeing that the vestry had contributed £5,000 and Mr. Passmore Edwards, after giving £10,000, an additional £3,000, and since last week a further sum of £2,000, making £15,000 in all, the Council ought surely to undertake the cost of maintenance. As to what they would do with the palace, it would become, practically speaking, a winter-garden, a palace of physical recreation, a small park with a roof. He wanted this palace as a rendezvous for 'Arry and 'Arriet as a counter-attraction to the public-house, the low beershop, and many other things which were demoralising to the labouring poor. After a long discussion, during which the recommendation of the committee was considerably amended, it was ultimately adopted in the following form:—"Subject to the freehold of Albert Palace and the ground attached thereto and the organ contained therein being acquired and handed over to the Council free of expense and any encumbrance and the building in good repair, the Council shall apply to Parliament in the next Session for power to accept the gift and manage and maintain the palace and ground as a place of recreation for the public; that provision be made in the Bill that the Council shall be free from the payment of local rates in respect of the Albert Palace and ground, and with power to the Council to make from time to time such reasonable charges for admission on such occasions as the Council shall think fit, with power to let all or part at a rental from time to time."

THEATRES.—XIII.

By ERNEST A. E. WOODROW, A.R.I.B.A.

NO review of the opinions of experts upon theatre panics would be complete without a full reference to Sir Eyre M. Shaw's views on the subject. Speaking especially of staircases, which is the point we must still further consider in this chapter, he says: "The auditorium proper cannot itself be subdivided, but the audience can be, and each portion ought to have a separate place for entrance and exit according to price, so that, in case of an alarm, or of anything happening which would require a sudden clearing of any part, there would be no obstruction at the immediate point of exit from the seats. It would be desirable that each portion of the audience should leave the building altogether by different passages, stairs, and doors, but this is not absolutely necessary for safety. If the several portions can leave their seats without obstruction, they may, without much danger, be allowed to join at some little distance; but in this case they should not be allowed to meet in a common passage either end on, or, if it can be avoided, even at right angles. It is much safer for the two streams to take the general direction of the common passage before they enter it."

The views of the L.C.C. as expressed in their tenth regulation differ somewhat from this, for therein two separate exits are demanded for every division of the audience, as already explained in a former chapter.

The London County Council's regulations require that staircases "shall be supported and inclosed upon all sides by brick walls not less than 9in. thick, to be carried down to the level of the footings." The actual wording in the present issue of the regulations is *footways*, but this is evidently a misprint. Mr. Nevill took great exception to a similar rule of the late Metro-

88. Lead pads to wall hooks:—

Where pipes are fixed with hooks a piece of lead is to be placed between the pipe and the

hook, and care is to be taken that the hook is not driven in so tight as to injure or contract the pipe.

89. Direction and inclination of pipes:—

All pipes to be laid to the direction and with the falls required, and all the falls are to be in the direction of the flow.

90. Bottom length of vertical pipe:—

The bottom lengths of all vertical pipes are not to be fixed until the work above them is completed, in order that all obstructions may be detected and removed before they are fixed.

BENDS.

91. Radius of bends:—

All bends to have wide sweeps, and the bore of the pipe to be kept full size throughout, and the lead of equal thickness. Dummies, and not bobbins and followers, to be used where possible in forming bends.

SOIL-PIPES.

92. Size of soil-pipes:—

Table of conditions under which 3½ in. or 4 in. soil-pipes should be used*:—

Diameter of soil pipes.	Number of w.c.'s to be served.	Class of trap under w.c.	Diameter of anti-siphonage pipe.	Height of top of soil-pipe above drain.	Height of top of vent-pipe above drain.
3½ in.	Not exceeding 4 tiers of single closets.	Anti D	2½ in.	Under 50ft.	Under 75ft.
Ditto	Not exceeding 2 tiers of double closets.	Ditto	2½ in.	Ditto	Ditto
4 in.	Exceeding 4 tiers of single closets.	Ditto	3 in.	Above 50ft.	Above 75ft.
Ditto	Exceeding 2 tiers of double closets.	Ditto	3 in.	Ditto	Ditto
Ditto	Exceeding 4 tiers of single closets.	Round trap or any trap other than anti D trap.	3 in.	Ditto	Ditto

* For buildings of great height, I should recommend that the height should be divided into sections, each division containing not more than four tiers of closets, and each division being fitted with a separate soil-pipe. This would prevent the traps of the lower closets being siphoned out by the momentum of the discharge from the top closet. This momentum would be very great in a building of eight or ten stories. In this arrangement the soil-pipes of the lower closets would act as the vent-pipe of the upper closets (See Fig. 18.), or separate vents might be provided for each soil-pipe.

93. Weight of lead soil-pipes:—

The soil-pipes, unless otherwise specified, to be of 8lb. lead.

94. Soil pipe inside of house†:—

Soil-pipes fixed inside the house to be of 10lb. lead.

95. Curved pipe at foot of soil-pipe:—

At foot of soil-pipe put a curved pipe next to curved channel in inspection chamber (see Fig. 19).

† Soil-pipes should not be fixed inside a house, unless it is absolutely unavoidable.

WASTE-PIPES.

96. Direction of waste-pipes and bends to do:—

Waste-pipes from all flushing-tanks and sinks,

FIG. 18

baths, &c., to be carried downwards in as direct a line as possible to gullies, drains, &c., and all necessary bends to be as easy as possible.

97. Wastes and traps of equal diameter:—

The wastes and traps of laboratory basins to be

FIG. 19

of one diameter—viz., 1½ in. traps and 1½ in. branch wastes.

98. Waste-pipes to discharge vertically into trap:—

All waste-pipes from flushing cisterns, sinks, baths, &c., to discharge vertically over the standing water in the gully.

99. Waste-pipes connected with gully:—

All waste-pipes from sinks, baths, &c., unless otherwise specified, to be fixed at foot into socket of oblique arm of gully.

100. Pipes discharging into heads:—

Waste-pipes discharging into open heads to be

FIG. 20

carried within 1 in. of the bottom of the head (see Fig. 20), and to discharge vertically into the pipe.

101. Wastes entering traps above standing water:—

All waste-pipes to enter traps above the level of the standing water.

102. Bath waste:—

Put 2 in. lead waste for bath.

OR. Put to Bath a 3 in. lead waste.*

* This should be used only to baths which have a correspondingly large outlet.

EXTENSION OF THE PUBLIC RECORD OFFICE.

THE designs of a new building intended as the first of a series of additions to the Public Record Office have just been prepared by the permanent staff of H.M. Office of Works, under the direction of Mr. John Taylor, F.R.I.B.A., surveyor of Her Majesty's Works and Public Buildings in London. The foundations will be completed in a few days, and tenders are now invited for the superstructure. The foundations are of Portland cement and gault bricks. In digging, the workmen came across several pieces of old pottery, which have been lodged at the Office of Works. The main, or Chancery-lane, front of the building will be Gothic in style, and faced with Portland stone and Kentish rag, harmonising with the existing building by Sir James Pennethorne. A second block to be built three years later will involve the demolition of Rolls House and connect the structure now in hand with the portion built some years ago. Subsequently, a third block will be constructed on the south side extending towards Fetter-lane, and the whole range of buildings will then form a quadrangle 40ft. wide. A considerable space will be left open at each end of the building. An arched roadway will give entrance from Chancery-lane to the quadrangle and thence to Fetter-lane. The north wing of the Record Office will be carried upon arches over the Rolls Chapel, and the shell of that 13th-century building, with its interesting monuments and its rich stained glass, will thus be preserved, and possibly utilised for the exhibition of some of the most remarkable documents in the possession of the Record Office. Rolls House will be taken down to make way for the north wing of the department; but a fireplace, some cornices, and the memorial standing in the wall over the seat formerly occupied by the Master of the Rolls when the building was devoted to legal purposes will be removed and preserved. The block now being built will cover a site 225ft. long and 65ft. wide in its broadest part, and consist of a basement and three lofty floors. The northern portion of the new building will be used for the reception of records and State papers, the southern part being reserved for the officers of the department. Elaborate precautions are being taken against fire, and the building will be as nearly as possible fireproof construction. The flooring will be fireproof; iron and stone are to be used for the staircases; the windows are to have stone mullions and iron lights, and the roof will be exclusively iron. There will be exceedingly little wood of any kind in the building. The repositories, entered in every case through iron doors, are to be about 17ft. by 24ft., and paved, for the better preservation of the papers, with oak blocks, closely sealed upon the concrete floor. Hydrants and other necessary appliances for fire extinction will be provided on each floor, and fireplaces will be erected only in the rooms of the officials; but the southern division of the building containing these apartments will be shut off from the other portion by iron doors. The remainder of the rooms will be heated by hot water obtained from boilers in the basement. Electricity will be the sole illuminant, gas not being introduced into any part of the building.

On Saturday, the consecration of the new chancel which has been added to the Gravesend parish church at a cost of £1,200 was performed by the Bishop of Rochester. The church was licensed for Divine service in 1497, and consecrated by Bishop Fisher in 1510.

Major-General Hutchinson, inspector of railways, was engaged during the whole of Friday inspecting the deviation railway No. 5 (Liverpool and Manchester), between Flixton and Urnston, accompanied by Mr. W. G. Scott, engineer of the Cheshire Lines Committee; Mr. E. Leader Williams, chief engineer of the Manchester Ship Canal Company, and the members of their respective staffs.

The fresh works added to the Museum of the Luxembourg on its reopening include M. Detaille's "Reddition de Huningue," Paul Baudry's "Portrait de Peyrat" and "La Vérité"; Meissonier's "L'Attente" and "Jeune Femme Chantant," left to the Luxembourg by the artist himself; a landscape by Pelouse, M. Carrière's "Maternité," a "Jeune Fille au Piano," by M. Renoir; M. Besnard's "La Femme qui se Chauffe," and M. Fantin-Latour's "Un Atelier aux Batignolles," with portraits of Manet and Zola.

Our Illustrations.

CITY OF LONDON SCHOOL FOR GIRLS.

This school owes its origin to the founder, Mr. William Ward, of Brixton, who died in October, 1881, leaving the sum of £20,000 to the Corporation of the City of London for the purposes of establishing a high school for girls to correspond with the City of London School for Boys; the school to be built upon land belonging to the Corporation at the time of the bequest. Considerable difficulty arose in obtaining a suitable site to answer this condition, but finally the Court of Common Council, upon the recommendation of the City Lands Committee, decided upon the site on which the new building is now being constructed, and situated on the east side of the middle road, not yet named, between the Victoria Embankment roadway and Tudor-street, and adjoins on the southern side the Guildhall School of Music. The site, which has an estimated market value of £10,000, has a frontage of 71ft. 6in. and a depth of 51ft. 6in., giving an area of 3,683ft. superficial. Owing to the nature of the ground it has been necessary to go down to a depth of 26ft. to obtain a solid foundation; the concrete is to be of Portland cement, and the brickwork of the basement will be carried up in cement. On the basement floor, the ceiling of which will be 3ft. above the level of the pavement of the street, will be placed the cloak-rooms, lavatories, and recreation room, as well as boiler-room, &c. On the ground floor there will be an entrance-hall, the lady principal's room, the secretary's office, and two class-rooms. The two floors above will have five class-rooms each, and on the third floor four class-rooms, each floor with a small lavatory and w.c. The rooms on the third floor will be provided with sound-proof doors of communication, enabling two or more rooms to be used together at once. On the fourth floor is arranged a luncheon-room, 70ft. by 28ft. 6in., and 16ft. high, with kitchen, &c. On the attic floor will be rooms for the housekeeper. A small lift will be provided for raising coals. The class-rooms will be 22ft. by 17ft., with two smaller rooms, 16ft. 6in. by 13ft. 6in., the height 13ft. in the clear. The floors will be of Homan and Rodgers' fireproof construction, with boards and joists over. The basement floor will be of asphalt on concrete. The warming will be by means of Boyd's ventilating stoves and hot-water radiators, fresh air being introduced to them; the extraction of vitiated air will be effected by valves opening into channels over the corridors, which will be connected with a shaft in communication with the furnace. The elevation to the street will be in the Anglo-Italian style; the material Portland

stone. The stairs will be wholly of oak. The architect is Mr. Andrew Murray (the City Surveyor); the builders are Messrs. Atherton and Latta. Accommodation is provided for 400 scholars at a cost of £16,000 for the fabric and a further £2,000 for the furnishing.

ST. PHILIP'S CHURCH, STEPNEY.
(For description, see page 789.)

COTTAGES, LONGFORD, KENT.

THESE cottages have been erected for Mrs. Tapping, at Longford, Kent, facing the main road from Sevenoaks to London, by Mr. Edward Bevan, builder, under the superintendence of the architect, Mr. Thomas Potter, of Sevenoaks. The materials used are, viz., for walls, good sound bricks, with light red facings, a slightly darker red tile for the weathertiling, and brown tiles for the roof, all supplied from the Danton Green Brickyard, close to the site.

HOUSE AT WEYBRIDGE.

THIS house was erected last year on the banks of the Wey, from the designs of Mr. J. Steward Taylor, A.R.I.B.A., at a cost of about £1,500. The materials are red brick and Broseley tiles. The cornice outside is of wood. The dining-room walls are panelled up to the ceiling. The work was extremely well carried out by the contractor, Mr. Albert Monk, of Lower Edmonton.

NEW HOUSE NEAR WINDSOR FOR THE DUKE OF SUTHERLAND.

THIS house is now in course of erection on a site abutting on the river between Windsor and Maidenhead. The materials used externally are red bricks and Winsley Ground stone, with carved brickwork at the bays, and porch in main front. The roofs will be of brindled tiles, supplied from the duke's tilery at Blurton. The interior of the hall will be panelled from floor to ceiling, and the dining-room will likewise have high panelled dado and ingle nook. All the ceilings of principal rooms are treated in simple manner of Elizabethan panelling and enrichment. The other portions of the house do not require description. The builder is Mr. C. F. Kearley, of Uxbridge and Kensington. The sanitary and hot-water work will be executed by Messrs. Bolding, and the whole will be carried out from the designs and under the superintendence of Mr. F. Lovell-Lee, of 14, Gray's Inn-square, for the sum of £4,613.

OLD HOUSE, ROUEN.

THIS is a good specimen of the old time domestic architecture to be met with all over Normandy. It is situated in a narrow street just outside the Booksellers' Court, which leads to the north porch of the Cathedral, and either formed part of the collegiate buildings or has been built on the site of them, and probably with their materials. Indications of pointed arches, now walled up to meet present necessities, may be seen in more than one place. Our illustrations are from original photographs kindly contributed by Commander Gladstone.

SOUTH PORCH OF ST. GILLES, CAEN.

It is somewhere stated that the Church of St. Gilles was originally founded by William and Matilda as a mortuary for the poor. If this be so no part of the original structure remains, and the porch shown in the picture is late fifteenth-century work. The church, as may clearly be seen, is disused, and more or less in ruins. The porch and its surroundings form a picturesque bit, heightened by the grass and wild flowers growing out of the crevices of the masonry. The church is situated close to the Abbaye aux Dames, which it faces.

HOSPITAL FOR INFECTIOUS DISEASES, KEIGHLEY.

THIS design was submitted in open competition, there being thirty competitors, and was placed second, receiving the first premium. The buildings are designed to accommodate thirty patients, divided over three pavilions, both sexes being equally provided for in each block. The administrative block provides for matron, doctor, six nurses, caretaker, &c., and the laundry block includes a two-stalled stable and ambulance, and near to, but isolated, is placed the mortuary. The entrance to the site is at the highest point, and the several buildings have been disposed so as to take advantage of the natural levels of the ground, which is situated on the side of a hill, and at the same time to be easily worked from the administrative blocks. The drainage would be disposed

of by subsoil irrigation on the Corporation land adjoining. Messrs. Marshall and Dick are the architects.

CHURCH OF ST. MARY MAGDALEN, OLD FISH-STREET, WITH ST. GREGORY-BY-ST. PAUL.

THIS parish church, which was rebuilt by Wren after the Great Fire of 1666, stood at the corner of Old Change and Knightrider-street. The name of Old Fish-street appears to have become obsolete. In the autumn of 1886 the church was again attacked by fire, which destroyed the roof, galleries, and internal fittings, leaving the external walls, which, being very substantially built of brick, faced with stone ashlar, remained comparatively uninjured till October last, when the work of demolishing the roofless and dismantled church was commenced, the site having been let on building lease by the Ecclesiastical Commissioners. The sketch shows the building as it stood in 1891. The tower stood at the north-west angle, and could be well seen from Lambeth-hill. The east front (towards Old Change) had three windows (the centre one blank) and an entrance-door, all similar to those on the south side. The church contained a monument to the Rev. R. H. Barham, author of the "Ingoldsby Legends," and Canon of St. Paul's, who was rector of the parish from 1824 to 1845; also a curious brass tablet, dated 1586, with the figure of a man and the following lines in black letter:—

"In God the Lord put all your truste,
Repente your former wicked waies,
Elizabeth, our Queene most juste;
Bless her, O Lord, in all her daies.
So Lord, encrease good counselors
And preachers of his holie worde,
Mislike all papistes desiers,
O Lord, cut them off with thy sworde.
How small soever the gift shall be,
Thank God for him who gave it thee:
If penie loaves to III poor foulkes,
Geve every Sabbath day for aye."

Both these monuments were fortunately saved from the ruins in 1886, and I am informed by the Rev. E. Hoskins, rector of St. Martin's, Ludgate, will be eventually placed in his church, with which parish St. Mary Magdalen is now united. Milizia, in his "Lives of Architects," says: "It has a nave and two aisles, and is 60ft. long, 48ft. wide, and 30ft. high. It is well-proportioned, and lighted by circular-headed windows."—CLARKE ASHWORTH.

ST. GREGORY-BY-ST. PAUL.

UPON the south-west side of Old St. Paul's Cathedral stood the parish church of St. Gregory, over which was the Lollards' Tower—"infamous, like its namesake at Lambeth, for the ill-treatment of so-called heretics." The church and tower are shown in the accompanying sketch, from a wood engraving of Old St. Paul's by Hollar, who was buried in St. Margaret's, Westminster. The exact site is marked by the present statue of Queen Anne, as will be seen by reference to the sketch plan, taken from Timbs' "Curiosities of London." The church was not rebuilt after the Great Fire, the parish being united with St. Mary Magdalen, Old Fish-street.—CLARKE ASHWORTH.

CHIPS.

Mr. Francis Braid, chief sanitary inspector, burgh engineer's department, Edinburgh, has received the appointment of sanitary inspector for the burgh of Kirkcaldy.

Plans have been prepared for the rebuilding of the Metropolitan Opera-house at New York, recently destroyed by fire, and it is hoped that the new edifice will be ready for the season 1893-4.

A feature of the forthcoming winter exhibition at the Royal Academy will be a selection from the water-colour drawings and designs of the late Marchioness of Waterford, including some of those exhibited last summer at the residence of Earl Brownlow, 3, Carlton House-terrace.

At a recent meeting of the Anthropological Institute, Major Temple drew attention to the new field of exploration offered by the caves of Burmah, which are rich in wooden carvings, glazed tiles, and images as well as tablets in terracotta, marble, alabaster, and other materials. These relics illustrate the ancient and modern phases of Buddhist worship.

The corner-stone of a new parochial hall for All Saints', Paddock, near Huddersfield, was laid on Saturday. The new hall will be Late Gothic in style, and is being erected from plans by Alderman Stocks, architect. The cost is expected, with furnishings, to be £2,000.

WAYSIDE NOTES.

FROM a bath-house to a polytechnic institute, and back again to baths. What will be the next move of this very volatile Erixton building?

The new Tate Gallery will be placed upon the site, or a portion of the site, of Millbank Penitentiary. According to a statement made by Mr. Shaw-Lefevre, M.P., two-and-a-half acres will be devoted to the picture gallery. Another portion of the Millbank site is to be utilised for the purpose of new barracks, a portion of the barracks behind the National Gallery being then moved to Millbank, thus leaving room for an extension of the National Gallery. This latter building, therefore, is destined to become greatly enlarged when the National Portrait Gallery is completed, and the contemplated further extension carried out. As to the remaining portion of the Millbank site, it has been offered to the London County Council, between whom and the Government negotiations are now pending.

In receiving a deputation of the unemployed on Monday last, Mr. Shaw-Lefevre gave an interesting *résumé* of the expenditures now being made by the Government in public works. There is the third new post-office, larger than any of the other buildings, now being erected at a cost of £200,000; and a new story on the old post-office is costing £25,000; while in Clerkenwell there is in course of construction a new parcel-office at a cost of £75,000. On the Admiralty extension £300,000 is to be expended; on an enlargement of the Patent Office and Record Office, £125,000 and £70,000 respectively. In addition, there are numerous minor works in progress. The deputation of the unemployed received a very considerate hearing from Mr. Shaw-Lefevre, who stated that he would endeavour to expedite new works immediately contemplated by the Government.

I fear that the increase of building works is not likely to remedy matters very much, it being shown that the depression and distress is less in the building trade than other industries. Shipbuilding is again reported in a depressed state, men from more yards being discharged on account of slackness of work.

"Cut-and-cover-in" puzzled us the other day. The originators of the term would seem to wish to be understood to mean thereby the excavation of a cutting in which the tube of a tunnel is constructed, the earth being subsequently filled in and rammed.

A very sensible suggestion has been made that, if instead of large sums of money being annually expended in promoting Channel tunnel and bridge schemes that have no chance of getting through Parliament, a small amount were devoted to the purposes of harbour improvements at Calais, the Channel passage in rough weather would be rendered less fruitful of discomfort to passengers who are not the best of sailors. There are two Bills for tunnelling or bridging the Straits to be laid before Parliament next session.

When the "House" meets, by the bye, it will not know itself. In preparation for the opening of Parliament, I understand that the Office of Works has pushed forward and completed sundry alterations in the two chambers. The House of Lords has been thoroughly redecorated, and the celebrated frescoes are being touched-up by Mr. Cope, R.A. No structural alterations have been effected in the House of Commons, but a large expenditure has been made on the lobbies, a new refreshment bar having been fitted up in the central hall on the site of the post-office. A lift for ladies from the Speaker's-yard into the corridor leading to the ladies' gallery is included in the improvements.

Among the mottoes of the competitors in the competition for the new Government buildings at Victoria, B.C., as printed in the *Victoria Daily Colonist*, I see "Ta-ra-ra-boom-de-ay." If we continue to be Americanised in competition mottoes as in matters, we may expect in the competitions of the near future, "Knocked 'em in the Old Kent-road" and "Up I Come with My Little Lot"—very suitable the latter.

In his "Fortunatus the Pessimist," recently

published by Messrs. Macmillan, Mr. Alfred Austin alludes to the "dim religious light" in—"Cathedrals where unfaltering twilight dwells, Subduing souls to sympathy and prayer."

It was perhaps a good instance of the truth of the position that over-refining of works and essays may take away much of their freshness, that it happened that a hurriedly prepared paper by Mr. Middleton on "Some Temples in Greece and Sicily" should prove most delightful hearing. Mr. G. W. Ussill being unable to read his paper on "Levelling and Contouring," Mr. Middleton at short notice was fortunately able to fill the threatened gap. I was sorry when the lecture came to an end, as with excellent lime-light views of grand old buildings, and the pleasant discourse thereon, one could have desired its extension to double the length. I always come away from a lecture on Classical architecture with a strengthened opinion that it has been left for a nineteenth century of supposed enlightenment to crystallise "orders" out of the architectural remains of Greece and Rome.

Herr Schwerzsch, a young sculptor of Vienna, has discovered that a small torso among the Parthenon fragments in the British Museum does not pertain to the piece of sculpture commonly imagined, but forms part of the boy who stands leaning against the statue of Leucothes in the west pediment. Ultimately, perhaps, the true nature of all the Parthenon fragments at the museum may be determined. One Museum mason has succeeded in properly locating nineteen fragments.

A paragraph in the last *Athenæum* is so much to the point, that I reproduce it completely in these pages:—"A startling appeal for £20,000 is now being made by the Chapter of Lichfield for what they are pleased to call 'the needful reparation' of their cathedral church. As this scheme includes the entire renewing of the roof upon what the architects believe to have been the 13th century lines, while the present roofs are thoroughly sound and excellent of their kind, we are astonished at the audacity of the language which the Chapter have sanctioned. The roofs and other parts of the church that it is now proposed to sweep away are chiefly due to the energy and skill of the great bishop of the Restoration period—Bishop Hackett. It is a monstrous thing to try to blot out this page of history as told in the fabric of Lichfield Minster."

So I think. The use of the term "needful reparation" is deceiving. Surely the idea of restoration back to a certain date has been long relegated to the past, along with other barbarous notions! We have advanced further than this, and are surprised that cathedral chapters or architects can be found to advocate such a plan. I trust that wide notice will be taken of this proposed "needful reparation" of old Lichfield Cathedral. As the *Athenæum* says, it is monstrous.

Winter gardens are most excellent institutions, and I am glad to see that the Brighton Corporation propose to erect such a building. In this climate, with its damp, cold, winter days and purely theoretical springtime, it is something for the people to be able to repair to some cheerful shelter, such as that afforded by winter gardens. Iron and glass being cheap in these days, there should be no excuse for seeing so few buildings of this class. That they are a source of great pleasure may be taken as certain, when we reflect that most men who build large mansions nowadays include a spacious winter garden. There should be more in London, and one at least in every town. I am glad to see that the County Council are taking over the Albert Palace for the use of the people. As the building has been generously offered to the Council if they will look after its maintenance and management, there should be no other course than that of accepting it. It will be a welcome resort for the inhabitants of Battersea. Similar institutions in other districts of London might well be brought into existence. They would have to be municipal affairs, as past experience has not shown glass houses of this kind in a favourable light as commercial speculations.

The annual dinner of the Society of Engineers will be held at the Holborn Restaurant on Wednesday week, the 14th inst.

OBITUARY.

WE regret to announce the death of Mr. Hugh Barclay, senior member of the firm of Messrs. H. and D. Barclay, architects, 245, St. Vincent-street, Glasgow, which took place on Friday night suddenly at his residence at 6, Buckingham-street, Hillhead, Glasgow. He was 64 years of age, and had been in the profession for 47 years. Mr. Barclay was a member of the Glasgow Institute of Architects, and acted on the Council of that body for a number of years. With his brother, Mr. David Barclay, who survives him, the deceased was the joint architect of the Greenock Municipal Buildings, built in 1879-82, at a cost of £120,000, the Glasgow Academy, and several churches and schools in Glasgow and Govan. A year ago he was predeceased by his wife, and leaves a family of two sons and three daughters. A portrait and biography of Mr. Barclay appeared in the *BUILDING NEWS* for July 4, 1890.

The death of Mr. James H. Bisset, of Aberdeen, builder, took place at his residence, Burnside House, on Thursday in last week, from heart-disease. Deceased was the only surviving partner in the firm of Messrs. P. Bisset and Son, builders. While a young man he emigrated to New Zealand. After his return to this country he took charge of the business which his father had founded, carrying out many important contracts in the city, among them being the building of Gilcomston Free Church, Rosemount Parish Church, Aberdeen Jute Works, and Rosemount Provision Works, and the laying out of Duthie Park. He was the first to use concrete in Aberdeen, and constructed the theatre in that city of that material. Mr. Bisset was a Liberal in politics, a justice of the peace for the county, and an elder in Free John Knox Church. Mr. Bisset was twice married, and was 55 years of age.

CHIPS.

The City and South London Electric Railway Company have given formal notice to the Lambeth Vestry of their intention to begin the construction of their extended line from the present terminus at Stockwell to Clapham-common, under the powers obtained by them under the Act of 1890.

Sir Frederick Leighton has received a memorial from the Sunday Society, bearing the signature of the President, Lord Brassey, and many past presidents, including Lord Rosebery and the Duke of Westminster, praying that the General Assembly of Academicians will take into consideration, on National grounds, the desirability of opening the Gibson and Diploma Galleries of the Royal Academy on Sundays.

A deputation of gentlemen waited upon the directors of the Midland Railway Company at Derby, praying that the company will construct a branch line from Padley Wood, on the Dore and Chinley Railway, to Millersdale, via Eyam, Hucklow, and Tideswell, a distance of nine miles, and so place Sheffield within twenty miles of Baxton. Mr. Turner, the Midland Company's manager, promised that an engineer should survey the route and report thereon.

The American School of Athens will shortly resume its excavations at Sparta, and at the Heraeum of Argos.

The operation of doubling the Somerset and Dorset line between Shepton Mallet and Binegar, which has been in progress for two years past, is now practically complete, and the new line was opened for traffic on Monday.

At the Llandudno Police-court last week Edwin Turner, described as an architect and builder, was fined the nominal penalty of 1s. and costs for obstructing the streets by leaving timber in front of a building in course of erection in Church-walk, Llandudno. The defence was that the practice was common in the town, to which it was replied that in future the commissioners would enforce their by-laws.

The dinner to the Worshipful Company of Plumbers is arranged to be given by the Lord Mayor as Master on Wednesday, the 14th inst.

A large block of livery stables in Silver-street, Bury, Lancs, was formally opened on Wednesday. The stables are two stories in height, will house 70 horses, and are fireproof throughout, the floor being of concrete. Messrs. Maxwell and Tuke, of Manchester, were the architects, and the contractors were Messrs. Thompson and Briery, of Bury.

A boot and shoe warehouse and offices, covering an area of quarter of an acre, have just been built in Mill street, Stafford. Mr. N. Joyce, of Greengate-street, Stafford, was the architect, and Mr. J. Jarvis, of County-road, in the same town, the contractor.

ArchitectTHE OLD REVOLUTION HOUSE,
WHITTINGTON.

THE village of Whittington, situate on the main road from Chesterfield to Rotherham, and about two miles from the former, possesses a few simple specimens of Old English domestic work. One of the least pretentious of these is the subject of the illustration. This cottage is a small portion only of the old Cock and Magpie hostelry, at one time an important wayside inn in these parts, and from time out of mind traditionally known also as the Old Revolution House. Here, we are informed, the Earl of Devonshire, the Earl of Danby, and Mr. John D'Arcy met on the eve of the memorable Revolution of 1688 to discuss important movements in furtherance of the plot for the overthrow of King James. For precise information as to where this meeting was held we are mainly indebted to the authority of local tradition, but that such a meeting took place at Whittington there appears to be ample written evidence to prove, the most authentic account being the references made by the Duke of Leeds himself (formerly the aforesaid Earl of Danby) in the introduction to his "Letters," printed in 1710, and quoted by the Rev. Samuel Pegge (afterwards Dr. Pegge), rector of Whittington at the time of the centenary celebration. Great demonstrations and rejoicings took place at Whittington in 1788 in celebration of the centenary of the Revolution, full accounts of which are recorded by local historians. Four years ago (1888) the bicentenary was celebrated on similar lines to its predecessor. At this time a generous offer was made by the owners to give the cottage to a committee of local gentlemen on condition that it be thoroughly restored and preserved as a relic of local antiquity. Lack of funds kept the project in abeyance for a long time, but at length the committee have taken the matter in hand, and the cottage has now been put into a substantial condition of repair, a considerable amount of restoration having become imperatively necessary, owing to the ruinous condition into which the place had lapsed in later times, a state of things not likely to recur now that the custody of the building has fallen into the hands of an interested and enthusiastic executive. It is to be hoped they will be followed by worthy successors, who will do their utmost to hand down to posterity this humble reminder of the great historical event with which it has become inseparably associated.

W. MARTIN ASHMORE.

ECHO IN BUILDINGS.

IN buildings of oblong form reflection or echo is often found due to the end wall and ceiling, and the angles formed by the walls and ceiling. Direct echo from the end walls, says Mr. H. C. Kent, M.A., in a paper read before the Sydney Architectural Association, "can be obviated by making the end wall elliptic, and by breaking it with recesses, or with a deep-stepped gallery, or by using absorbent materials, such as draperies; while secondary echoes can be greatly obviated by cutting off the angles with a curve, as well as by slight breaks in the side walls which will prevent the conduction of the waves along their surface." Deep square recesses in the walls, except in the end opposite the speaker, and deep square openings in the ceilings, such as lanterns, should be avoided, as these breaks serve to set up vibrations of a conflicting kind. Wood lining is recommended for the walls and ceiling by most writers; but Mr. Kent thinks it increases resonance and detracts from clear definition of speaking. The author thinks simple harmonic proportions desirable in buildings intended for music, such as the ratio 2 to 3 to 5, or 2 to 2 to 5, the first of these being that of the Free Trade Hall, Manchester; the second that of the old Surrey Music Hall. The Sydney University Hall has the dimensions 135ft. by 45ft. by 68ft. high, and these are found to give satisfactory results.

ST. PHILIP'S CHURCH, STEPNEY.

THIS cathedral-like church, erected at the cost of the vicar, the Rev. Sidney Vacher, was opened a few weeks ago, though the tower has yet to be built. The building was commenced in 1889. Mr. Arthur Cawston, A.R.I.B.A., is the architect; Mr. T. Higgs was the clerk of the works; and Messrs. A. Bush and Sons are the builders. The accompanying sheets of illustrations show some of the general drawings of the church, and we shall follow them up by a series of views and working drawings. The aim of the vicar was to build a perfectly useful building capable of seating a great congregation gathered in from his crowded and populous parish, situated to the rear of the London Hospital, Whitechapel, and the architect was instructed to design a structure worthy of Divine worship, making it bright and interesting as a refuge from daily toil and a bright spot 'midst squalid surroundings. The

nave is narrow, and the choir is short; but the wide double aisles afford ample space. Over the narthex in the tower there is a deep gallery. The morning or Lady-chapel is in the orthodox place to the east of the sanctuary, and its design somewhat corresponds with the plan of the similar chapel at Wells. This is an accident, however, as Mr. Cawston was unaware of the coincidence till after he had made his design. The centre pier is of Hopton Wood stone, supporting the vaulting, and the walls are faced with Sussex stone from Three Bridges, with the masonry in small scantlings. Common stock bricks are used for the general facing of the walls of the church, which are relieved with Bath stone dressings. Ancaster stone is used externally, with red brick for the walling. The cloister and chapter-house-like arrangement south of the church, makes a great feature in the plan, adding much to its interest and dignified approach. The lofty proportions and refined detail of the church may be readily judged by the scale drawings, which we now publish for the first time. The seating is mainly by chairs. The font is handsome, and has a spire-like cover suspended from the baptistery roof. The cost was, we understand, about £40,000.

NOTES FROM PARIS.

AS I remarked in my last letter, the question of sanitary improvements at Paris is much talked over.

The "tout à l'égout," or system of total drainage, is that which will most probably be adopted. Unfortunately several trials which have been made in a rather incomplete fashion have turned the Parisian public against this system, but further successful trials will surely turn the opinion in favour of the adoption of the "tout à l'égout." The soil and matter from Paris will be drained into the country as far as Aubervilliers, where it will be converted and used for industrial purposes. The important question at present is to efficiently flush the system of drains, with the least possible waste of water, for Paris at the present moment is very scantily supplied with water, and especially potable water. For this reason a number of ingenious apparatus destined to avoid as much as possible the waste of water have been submitted to the sanitary authorities. That which seems to be most

certain in its working, and which has as far as present been approved of by the Municipal Council, is a system invented by Monsieur Lafforgue, architect; and as this may interest some of your readers, I subjoin a sketch drawing of the apparatus.

It works automatically, and by means of compressed air, and, according to the inventor, will save nearly 70 per cent. of the water now wasted in drainage of water-closets. The apparatus is exceedingly simple in arrangement, and, what is a great thing in the eyes of house proprietors, may be adapted to the system of closets at present in vogue. The down pipe B falls into a tank G of general dimensions about 20in. by 16in. by 14in. This tank, which is hermetically sealed, is furnished with a siphon of large diameter (5in). The tank is fed by a service pipe of very small diameter, allowing a very small quantity of water to gradually fill the tank. Rain and slop water may also be allowed to run into the tank. The soil, &c., falls by the down pipe into the tank, and there mixes with the water contained in the tank. The air in the portion of the siphon between O and P is compressed to a more or less degree. As soon as the level of the water in the tank attains the point C the air in the pipe between O and P becomes compressed to a great degree, and this pressure overcoming the water-seat P forces the water into the drains, and starts the siphon O, the whole contents of the tank being rapidly and forcibly drawn away into the drain pipes. This takes place each time that the water attains the level C. This apparatus has been tried in several

houses, and works very satisfactorily. Of course, as far as the science of sanitation is concerned, it can hardly be called a step forward, but still the adoption of such a contrivance is absolutely necessary for the present at Paris, where water is so scarce.

Since the cholera scare the "Assistance Publique" has been making great strides in the improvement and enlarging of the general hospitals. At the Hospital Cochin a large number of isolated buildings are being rapidly constructed, and in a new material about which I should like to speak later on.

The Pantheon is beginning to show signs of great deterioration in different parts, and the immediate attention of the council has been asked, in order to take the necessary steps for repairs. The first stone of this immense building was laid in 1764 by Louis XV., and the peristyle, with its twenty-two columns, supporting a triangular pediment, was considered a *chef d'œuvre*. The work in the pediment by David d'Angers has for subject "The Country Distributing Palms to its Great Men," and contains figures of Fénélon, Lafayette, Carnot, Voltaire, and Rousseau, and

other great men of the past day. A short while ago an immense block of stone, forming a portion of the sculptured work fell, and other portions are in imminent danger of following.

The works at the Buttes Montmartre are being recommenced; the gardens are nearly completed, and the large grotto over which will fall the water of a large waterfall is finished. The artificial rocks and rustic stairways are being rapidly formed. A large sum of money has been voted by the town for the full completion of these works, and it is said that these gardens will form one of the great curiosities of Paris.

The Minister of Fine Arts has named M. Roger Ballu inspector of fine arts at home and abroad; M. Armand Silvestre taking the place of M. Ballu as inspector. M. Delair is named "conservateur" of the Museum of Sculpture at the Trocadero.

At the Ecole des Beaux-Arts the prizes and medals for 1892 have been awarded; the Grand Médaille d'Emulation to M. Desperthes, who also carries off the Prix Abel Blouet.

In the concours of this past month, the subject being "A Prefecture for a Maritime Department," there was no first medal. Second medals were taken by MM. Durand and Bertrand, students belonging to the studios Redon and Gaudet. The subject for the sketch designs was "A small dock for gondolas in a park surrounding a sumptuous dwelling." Two medals were awarded for their sketch designs to M. Hulot and M. Pille.

The sketches for the interior decoration of the entrance rooms of the Salle de Fêtes of the Hôtel de Ville have just been exhibited at the Palais d'Industrie. The decoration comprises the walls, ceilings, and friezes of the two entrance rooms, the prize for the winning artist being about £2,500; there are also two other premiums of £120 and £80. Three hundred artists offered to compete, but only fifty sent in sketches for exhibition. The subjects chosen by the different artists were most varied. Mythological subjects abounded. There were several designs representing the friendship of France and Russia, a certain number contained views of Paris, the Madeleine, Champs Elysées, &c. Six artists are chosen to compete in the second degree of the competition. These are MM. Bonis, Danger, Delance, Ferry, Martin, and Simas. This final competition will be adjudged in April next.

It is the intention of the authorities to construct a Columbarium near the crematory furnace in the cemetery of Père La Chaise. The idea is to unite in one group all the services necessary to cremation, and form a kind of necropolis reserved for incineration. The monument, after the drawings of M. Fornigé, will present a double portico, divided longitudinally by a wall to contain the urns. This portico will surround the crematorium. The estimate for the building is nearly £30,000. Perpetual leases will be granted for £14 each urn, a fifth of this sum being devoted to charities.

The Union Syndicate of French Architects have decided to participate collectively in the Chicago Exhibition. The works will be represented by photographs, and divided into four sections—public monuments and schools, &c.; churches; private buildings, hotels, and smaller work; and industrial buildings. Casts are being taken from the finest of the architectural casts in the Trocadero Museum, representing French architecture, and these are being sent to the Chicago Exhibition.

The Association of French Architects has just sent in a petition to the Senate asking the Government to allow a free competition amongst French architects for the proposed new Opera Comique if, perchance, the design which has already been adopted should for any cause be put aside. The design submitted to the Theatre Commission, as far as present adopted, is due to MM. Duvert and Charpentier, architects. The adoption of a design not sent in in competition is much commented on here. The Parisian architects have thus decided to send in the petition, asking for a general competition, as was done for the Grand Opera in 1860. The building will be constructed on the site of the old Opera Comique, which was burnt down. The façade will not be on the Grands Boulevards. The total surface occupied will be about 16,000 square feet; a large amount of iron will be employed in the construction. The new theatre will have 1,514 places, instead of 1,598 in the old building, and will be entirely fitted with the electric light.

I hear since that the Provincial Societies of

Architects are also sending in a petition asking for a general competition for the Opera Comique. In July last, just before the closing of the Senate session, a vote was carried approving the reconstruction of this theatre by means of a financial combination proposed by four well-known contractors. The estimate for the building was about £140,000, the State allowing about £50,000 of the amount, the remainder being borrowed from the contractors, and repayable by the rate-payers in 76 years. M. Guillotin, the principal contractor, ordered and sent in designs which have been accepted by the Senate. The French architects are therefore justly annoyed at this manner of doing things, instead of either choosing a thoroughly qualified and well-known architect to get out the plans and design, or making the theatre a subject for competition.

ARTHUR VYE PARMENTER.

COMPETITIONS.

GATESHEAD-ON-TYNE.—The Gateshead School Board selected on Wednesday the designs in the competition for new schools at Shipcote. Nineteen plans had been sent in by architects practising in the counties of Durham and Northumberland, undistinguished by either name or motto, and each of these was marked by the clerk to the School Board with the name of a county. They were then hung for public exhibition during the past fortnight. At Wednesday's meeting the first place was awarded to Mr. Stephen Piper, M.S.A., County Chambers, Newcastle-on-Tyne, who was appointed architect of the schools; the plans by Mr. John Thompson, Newcastle, being placed second, and those by Mr. Pritchard, of Darlington, third. The schools are for 1,000 scholars, in three departments, and the cost was restricted to £7,000. The chief points in the selected plan were the skilful use made of the fall in site, left-hand and double lighting to every room, and compactness of arrangement. The basement of two departments is utilised as a gymnasium and cookery class-rooms, while a drawing class-room is placed in roof with north light.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

THE A.A. LYRIC CLUB.—The second concert for the present session of this social auxiliary to the Architectural Association was held at the old headquarters, the Mona Hotel, Covent Garden, on Friday, November 25th. Messrs. Percy Smith and C. O. Law were responsible for the programme, which included performances by Messrs. A. G. Turner, J. D. Butler, S. Richards, H. F. Hepburn, E. A. Lambert, C. O. Law, W. G. Churcher, H. Seton Morris, C. D. Imhof, and the A.A. String Band. The next concert will take place on Friday in next week, the 9th inst., and will be arranged by Mr. A. W. Earle. The club's annual Cinderella dance will be given at the Portman Rooms, Baker-street, on Wednesday, February 8th.

CHIPS.

A stained-glass window, presented to Esrick Church, near York, by Mr. and Mrs. J. G. Menzies, of Esrick Park, in memory of the late Duke of Clarence, was unveiled last week.

In recognition of the public services of the late Viscount Hampden, it has been resolved to place in the County Hall, Lewes, a copy of the portrait by Frank Holl, representing Viscount Hampden in his robes as Speaker of the House of Commons, and hung in the Academy of 1885. The cost will be defrayed by a county subscription.

A Bill for powers to construct an electric railway from Brighton to Rottingdean will be introduced into Parliament next Session. This railway, which will be nearly four miles in length, will commence near Preston Park, Brighton, and proceed along the beach and foreshore to Rottingdean. From the termination of the railway a jetty is to be constructed 200ft. into the sea.

A memorial rood screen was dedicated at St. Alban's Church, Leamington, last week. It is in 14th century style, and consists of a series of five cusped main arches, the centre one being much wider than the two on each side. Over the arches are canopies, with carved crockets and finials, and open tracery surmounted by an embattled cornice. The work has been executed in wainscot oak by Messrs. Cornish and Gaymer, of North Walsham, from the designs of the architect, Mr. William Bassett-Smith, of John-street, Adelphi, London.

Building Intelligence.

BEDMINSTER, BRISTOL.—St. Paul's Church, Bedminster, built in 1831, was reconsecrated on Wednesday week, a new chancel having been added to it. Formerly the church, although a large one, had as chancel a space of only a few feet, and the work just completed has lengthened the church eastward for a considerable distance, and provided a minister's vestry on the north side and an organ-chamber in the south of the addition. This alteration has been accompanied by a reseating of the edifice, open varnished pitch-pine pews being substituted for those formerly in use. The new chancel has a dark timber roof and a large eastern window, below which is a reredos. The organ has been shifted from the east end of one of the galleries into the organ-chamber, and the choir have seats in front of it. Mr. A. Barnes, of Bristol, was the architect, and Mr. Humphreys the builder.

EAST BARRY.—The ceremony of laying the corner stone of the new St. Paul's Church, East Barry, was performed on Tuesday. The church is designed in the 14th-century character, and to seat 530 persons. It is to be built of Catbybrook brick, both inside and out, with Bath stone dressings. There will be a nave, 70ft. by 24ft., with north and south aisles 10ft. in width, chancel 32ft. by 20ft., together with a south chancel aisle, organ-chamber, and vestries. The arcade is of pitch-pine, with traceried spandrels and octagonal shafts. The roof of the nave is an open-timbered one, and that of the chancel a barrel one, with moulded ribs. The tower is placed at the west end, and is open to the nave by a high arch. The roofs will be covered with Welsh green slates. The present contract is for the nave, south aisle, and heating-chamber, at a cost of about £2,000. The architects are Messrs. Kempson and Fowler, Llandaff, and the builder is Mr. Wm. Richards, jun., of Barry.

MOLD.—The new English Presbyterian church, Mold, was opened last week. The style is Gothic, and the church measures internally 53ft. 6in. by 45ft., and has accommodation for over 450 persons. The plan is arranged with circular pews, which incline towards the pulpit, and are constructed in a gallery form at the sides and back. The building is designed in one span. At the rear are the school buildings, which consist on the ground floor of a schoolroom measuring 28ft. by 27ft., to accommodate 200 persons, and three classrooms. A lecture-room, seating 250 persons, is constructed over the latter, and also forms an additional schoolroom. The walls are built of stone. On the west side of the front façade, and occupying the angle of site, is a tower with spire. The organ-chamber is formed in the side transept, and projects from the main building, and the walls are finished in a gable. The principal roof timbers are exposed and varnished. The interior is fitted up in pitch-pine, with pitch-pine wainscoting and pulpit. The church and schools are heated with hot water on the high-pressure (small bore) system. The builder is Mr. Roberts, Mold; the clerk of works Mr. Roberts, Ruthin. The architect is Mr. T. G. Williams, Liverpool.

We are requested by Mr. Archer to say that he was assisted in the completion of Hyde Park Court, illustrated last week, by his partner, Mr. Francis Hooper, A.R.I.B.A. As to this illustration, we omitted to state that the large spiral staircase, so elaborately detailed in our description of the building, the balcony railing, verandahs, and a portion of other ironwork were all supplied, to special designs, and fixed by Messrs. Steven Bros. and Co., of 4, Upper Thames-street, E.C. The spiral stair in question is 7ft. in diameter, and is the largest of the kind in London, with the exception of the one erected at Messrs. Steven Bros. and Co.'s own showrooms at 4, Upper Thames-street, which is well worth inspection.

On Saturday, the last link in the direct overland communication between England and Gibraltar was completed by the formal opening of the Algeiras-Bobadillo Railway, the final section of which, that between Rhonda and Algeiras, opposite the peninsula of Gibraltar, has now been finished. Mr. James Ffiorde is the engineer of the work, by which the journey from London to Gibraltar has been reduced to sixty hours.

A scheme is being promoted for the construction of a line from Tollesbury, a fishing village at the mouth of the Blackwater, to join the branch of the Great Eastern Railway from Witham to Maldon.

Correspondence.

THE INSTITUTE AND ITS ASSAILANTS AND APOLOGISTS.

To the Editor of the Building News.

SIR,—In a work recently published, "Architecture a Profession or an Art," I find that an address to the Royal Institute of British Architects, which I signed, is placed at the head, as a sort of text for an attack on the Institute.

When I signed this document a serious attempt was being made to obtain legislation for what is termed "closing the profession." The Institute was petitioning the House of Commons against it, and it is a step to which I see very great objection. I signed in all good faith with the Institute, and I think that I might have been consulted before my name was used so as to appear hostile to it.

With regard to the Institute examinations, I feel sure that the healthy stimulus they give to exertion and study is very decidedly advantageous. Before they existed no means were available by which to ascertain whether an applicant for admission had any real qualification for his work. Surely it is a step in the right direction to encourage men to study, and show that they have done so to some effect.

I should be glad to see another step taken, by which the Institute would become a teaching body. For the present, it has taken the line of assisting the ever vigorous Association in the work of education, and perhaps they will work together on broader lines than if they work singly.

There seems to be no reason why the Institute should not assist in the education of designers and artificers of all classes connected with architecture; but that happy time will be more speedily brought about if those who desire it use their influence to promote it, instead of holding aloof, with the apparent object of driving the Institute into narrow ways.—I am, &c.,

Cambridge, Nov. 28. W. M. FAWCETT.

"SEASIDE ARCHITECTS."

SIR,—It would be interesting to learn if the letter under the above heading, in your issue of the 18th inst., is intended to be taken seriously, or as an unwitting sarcasm on the writer himself. Whatever are the ways or customs of "the profession," it is quite evident that "young architect, fresh from a first-class office," has quickly adapted themselves to their modes and manners, as I will prove. In the first place, I may say that I do not object to advertising, but I do detest any posing under a false attitude, or acting the part of a Pharisee; let us have a truthful statement of the honest facts.

As to the merits or demerits of advertising, I will not enter, as in this locality we are compelled, in self defence, to adopt methods which may appear strange to our southern brethren. But the most amusing portion of the letter is the reference to the "sheet of elevations," as the producers of that have only been in practice between twenty and thirty years, and have only acted as the architects for the Manchester Exhibition, Blackpool Tower, and sundry other small jobs. This assumed indignation is even greater than the usual pretence we are accustomed to from young architects; but I will vouch that if that gentleman had erected any buildings worth showing he would have acted just the same, or, probably, gone even further. When I finished perusing the afore-mentioned epistle, I went to view some property now being built under a certain "young architect," expecting to have a treat; but, "ye shades of Pecksniff," what did I see?

More prominent than anything, a huge advertisement—no, I beg pardon, I meant "information" board—with the same letters on it that form your last week's correspondent's name. I suppose we all have a double, and therefore, that must account for the strange coincidence (to put it as mild as possible); but, all the same, I would strongly advise "young architect" to compel the double to destroy the advertisement, as it must be a vile libel, and just the opposite of the sentiments and views of the writer of the oracle afore-named. And it must be the double also (good old double) who put an advertisement—no, I mean "information"—paragraph (you must kindly excuse me, as in this country we call a spade a spade) in the local papers intimating—

well, just the usual thing—not, perhaps, "Plans prepared on the shortest notice, at so much per yard," but the same idea, only arranged in different form and words.

"Young architect" had better be looking up that "double," or it may bring a distinguished name into disgrace, and be the means of blighting the hopes of a first-class office, and of the public saying the "whitewash brush" has been extensively used.

And now about the building I have referred to. When I examined the elevation, I fully coincided with the last paragraph of "young architect's" letter—viz., "as regards the architecture, the less said the better." Perhaps, however, the public taste has not been sufficiently cultivated to appreciate the superior design of the building (especially the windows). By the way, I should be glad to know if it is intended that the joints of the bricks are to be used for ventilators, as they are "very fine and large," and also if it is correct that one person asked, when he saw the window jambs, "if that weren't an old bed-post petrified?" or is it to be a furniture shop, without any sign-board?

I will not trespass any further upon your space, but trust that in the process of "settling down," "young architect" will not be let down too low.—I am, &c.,

HENRY BANKS,
Head Assistant in Another First-class Office
in the North of England.
St. Anne's-on-Sea, Lancs.

RE PROPOSED NEW BATHS FOR CHELSEA.

SIR,—Wishing to compete for these new public baths, I sent the usual fee for the conditions of the competition; but finding that nothing was framed in the conditions to protect the competitors, I am obliged to withdraw from the competition.

The two principal points that I object to are contained in a letter just received from Mr. Henry Wright, the clerk to the commissioners, a copy of which I inclose, and trust that all architects who value their time and self-respect will at once withdraw from the competition.—I am, &c.,

R.

The Commissioners for Public Baths and Wash-houses in the Parish of Chelsea.—171, King's-road, Chelsea, 24th Nov., 1892:—

DEAR SIR,—I am directed by the Commissioners to acknowledge the receipt of your letter of 18th inst., and to inform you that the Commissioners do not intend to appoint an assessor. The Commissioners do not bind themselves to adopt any of the designs.—Yours faithfully,

HENRY WRIGHT,
Clerk to the Commissioners.

To "R."

Since then I have received the following letter from the Secretary:—

The Commissioners for Public Baths and Wash-houses in the Parish of Chelsea.—171, King's-road, Chelsea, 29th Nov., 1892:—

DEAR SIR,—I beg to acknowledge the receipt of your letter of 28th inst., and to return herewith your cheque. I may say that it was the intention of the Commissioners to appoint an assessor, but that being unable to obtain definite information as to the amount of the fee required, the proposal was abandoned.—Yours faithfully,

HENRY WRIGHT,
Clerk to the Commissioners.

To Mr. "R."

New Exchange Buildings have been erected at Newcastle-on-Tyne, and special attention has been paid to the ventilation, which is carried out on the Boyle system, the latest improved form of the self-acting air-pump ventilator being adopted for the extraction of the vitiated air.

Major-General Hutchinson, C.B., inspector from the Board of Trade, inspected on Tuesday the new line constructed between Huddersfield and Fartown, via Birkby, giving an alternative route to that part of the borough. The new line is $1\frac{1}{2}$ mile in length, and the new route is along John William-street, St. John's-road, Wheathouse-road, Birkby Hall-road, and Spaines-lane. The steepest gradients on the line are 1 in 12, 1 in 4-23, and 1 in 14-29.

Mr. Yates, coroner, opened an inquest at Crewe on Monday, on the body of Janet Vincent, wife of George Alfred Vincent, architect. The husband stated that on Wednesday last he gave up his house in Ridgway-street, Crewe, with the intention of going to Stockport. On the way to the station his wife was taken ill, and she had some brandy. As the railway officials considered her too ill to travel, they returned into the town, and about midnight both he and his wife were taken to the lock-up by the police. The next morning they were discharged. Dr. Moody was called in the following day, and found the woman dying. In his opinion, death was due to excessive drinking. The coroner severely questioned the husband, and adjourned the inquiry for further witnesses.

Intercommunication.

QUESTIONS.

[1901].—**Colouring Dirty Cement Stucco.**—I wish to colour some old cement stucco to match new. Is there any way of mixing Portland cement to form a permanent wash? If so, please state method.—**BUILDER.**

[1902].—**Measuring Walls.**—A dispute has arisen between an architect and a builder as to the proper way of measuring walls of various thicknesses. In the "quantities" the wall was stated to be so many perches, but nothing was said about the thicknesses or local customs. The walls were of various thicknesses, from 8ft. 6in. to 1ft. 6in. The builder now claims extra on quantities, and says the walls are to be reduced to a uniform thickness of 18in., according to local custom; but the architect will not allow it, and says that all walls must be measured superficially without considering the thickness. Will any reader oblige by giving his opinion as to the proper way.—**SOUTH WALES.**

[1903].—**Washable Distemper.**—Will some one please say how this is made and applied?—**BUILDER.**

[1904].—**Painting Roman Cement.**—Can Roman cement be safely painted sooner than Portland?—**SAP.**

[1905].—**Valuer's License.**—I should be glad to know through some of your correspondents what is my legal position with regard to valuer's or appraiser's license. I am frequently called in to make valuations for mortgages, and have up to a short time ago held such license, but am told that I have no necessity to do so, inasmuch as the valuation is not obligatory between parties. I may say that I have mentioned this matter to the Inland Revenue Officer, and he is not quite clear on it himself. I may also add that I do not have on my office sign the word valuer, but simply architect and surveyor.—**INQUIRER.**

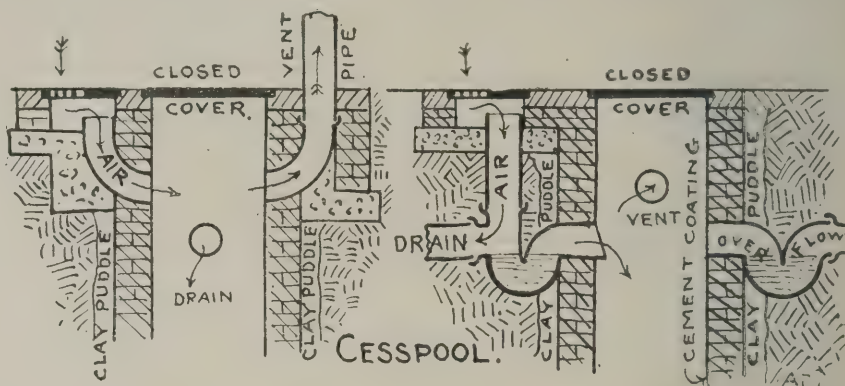

[1906].—**Chemical Burning.**—I shall be glad of some information as to the process of jointing leadwork which goes by the above name. What is the *modus operandi*? What is the acid which is used, and its price? How does the labour compare with soldering as to time occupied? Is the work a speciality—that is, is a workman entitled to anything over ordinary trade-union plumber's wages? Answers to these questions and references to textbooks will be esteemed a favour.—**W. X. Y.**

REPLIES.

[1873].—**Boasting.**—On the 21st Oct. "One Who Wishes to Learn" inquired what was "boasted" work, and on 28th Oct. N. Joyce replied that if he visited a freestone mason's yard he would see a broad chisel inch wide called a "boaster" in which faces and, in good work, beds and joints were finished. On Nov. 14th "One Who does not mind Telling" says "boasted" work means parallel lines about 10 to an inch on the face of the stone, vertical when well done, but if badly done at an acute angle, and that a boaster is a chisel 2in. or 2in. wide. On 11th Nov. "A Mason" really tells what boasting is or was as I knew it years ago when I often stood at the safe side of a banker. "Boasted" may be phonetic or local, but whether right or wrong as to the word, he is right as to the work, which is roughly preparing for a finer finished face. "The One Who Told" in this week's "B.N." takes "Mason" to task for correcting him with a horny hand rather than a kid glove, even if out at the finger-ends, and demands that "authorities" and "rebutting authorities" be quoted. This only shows that he knows more of books than bankers, and of boasting with a pen's point than with a mallet and tool. Still, his reference to authorities is not happy, for those he mentions that I have at hand do not support him. Parker's "Glossary" says "to boast is to block out for carving." "Nicholson" old ed., describes boasting as "paring the stone irregularly with a broad chisel and mallet, and in carving rough-cutting the outline," &c. Gwilt says, "In London the tools used to work the face of a stone are successively the point, the inch tool, the boaster (the operation of working with which is called boasting, as that with the point is called pointing), and the broad tool." This should be sufficient authority for "The One Who Told," who should not only be glad to be corrected by a practical man, but should not raise side issues on orthography, or on large or small areas, or the width of chisels (as to which he confounded a "boaster" with a "broad tool"), or fling authorities at the head of "A Mason," who possibly may be a better authority on the subject than all the authorities mentioned rolled into one. But all this is beside the original query, "What is boasted work," which "A Mason" has answered, and "The One Who has Told" has only proved that he, like Goldsmith's schoolmaster, "even when beaten could argue still."—**M. M.**

[1873].—**Boasting.**—Your correspondents appear to have somehow got very much mixed on this subject, and I will try to help them out of the misunderstanding. It is now some 24 years since I worked as an apprentice stonemason, and the following is what I remember of the subject of inquiry: The process of "boasting" is the last effort of the working mason to finish a straight or even surface on the stone, and is usually done with a tool from 2in. to 3in. wide. No good or sensible mason would endeavour to use a boaster at right angles to the bed of the stone, nor would he on the other hand use it at anything like an angle of 45°. I never saw a specification which said that he should do so. The question of how the word is spelt is, I think, a matter of little moment; but I am sure that "boasting" is the word most in use and best understood by masons generally. I remember one or two masons in my life who always referred to the tool as a "booster," and the use of it as "boosting," and I believe that they hailed from the North Riding of Yorkshire, and probably your correspondent, "A Mason," is of that ilk. The process of tooling, which has so unaccountably become mixed up with boasting, is a different process altogether, and is simply of an ornamental character. The idea seems to have been to make each stone in a building look as if finished by one machine, and as scarcely any two masons could be found to tool exactly alike, it was usual to select one or more masons (according to the size of the building) to tool the exposed surfaces of all the stones worked by the other

masons engaged on the building. The process consisted in making a series of small hollows close together in the face, and always at right angles to the bed of the stone. Each separate hollow was made by one blow of a mallet on the head of a tooler, repeated as many times as would cover the full depth of the stone in hand, thus completing one hollow before commencing the following one. The tooler was usually 4½in. wide, and was made spe-

cially for tooling. It could not be used for any other purpose in masonry on account of its breadth and consequent weight. To insure even work the face of each stone was finished as straight and smooth as possible, and in many instances rubbing (with stone or iron and sand, with water combined) was considered necessary to make an even surface for the tooler to rest upon before being struck with the mallet. Tooling is now little used in this country, except for improving the appearance of the exposed surfaces of tooled flags, landing steps, and street kerb. This is done by men at the quarries in a very rough manner by making marks with a tooler about 2in. or so apart. I should recommend "The One Who Told" to find a mason of the old school who was at work, say, 35 years ago in any of the Yorkshire (West Riding) manufacturing towns, and take him as an authority. I am afraid that the Manchester mason who sampled the boasting must have been like the man who made Chrysores (as Galatea has it) "only a beginner." What I have written refers to sandstones generally, or hard limestones. The working and finishing of soft oolites or freestone is another matter.—**A BUILDER.**

[1873].—**Boasting.**—I have no desire to appear harsh, and perhaps your correspondent is justified in taking exception to the manner of my reply in your issue of Nov. 11th. I think it must have been caused by the title he took. As to his list of books and authorities, these are all very well in their way, but they are not of much use in instructing workmen. I will at once concede him the point of spelling "boasting." I have seen it used both ways, and it does not really affect the issue. I may add that many architects say "boosting," so I suppose I am in good company with regard to it. I maintain that the description of work he gave in your issue of Nov. 4th is "tooling" pure and simple, and an excellent description it is, except as to tool used for doing it. Boasted work is very different, and is nearly always done to an angle, and varies with the texture of the stone as the number of blows to the inch. A "tooler" is a tool 4in. to 5in. wide, and a "boaster" is 2in. to 2½in. I never said that a "boaster" was 4in. wide: the vertical lines or blows in tooling are usually done after the work is boasted. Sometimes on very excellent work it is rubbed before tooling. I may say that tooling is really done more as ornament, and requires to be done fine, whilst boasting is really a levelling of the surface, and the boaster often takes 1-16in. or so of the surface of the stone, thus in a manner dressing it. I think your correspondent cannot have read my answer very carefully, or he would not ask for an authority showing a boaster to be 4in. wide. This is a tooler, and is the one used to produce the kind of work he describes as boasting. I think that a discussion on paper on technical subjects is nearly always unsatisfactory, and would suggest that he takes the correspondence as it stands, and submit to the judgment of the Manchester district. As he appears to hail from the Manchester district, I would have no objection to meeting him, and to this end I enclose full particulars with the object of a friendly conversation on the matter. This is my last communication on paper. I am quite willing to abide by the judgment of the trade. As to custom in the North and Midlands, there may be some exceptions. I spoke generally.—**A MASON.**

[1886].—**Breaking Weight.**—In the multitude of counsellors there is wisdom, and two heads are better than one; but "Student" will hardly be able to perceive which of the three answers to his query is the correct one, therefore I step in as arbiter. "Essex" and "Sien Seng" have omitted to notice that the column comes under the denomination of short, and have not made the consequent correction. The answer given by Mr. R. J. Angel is the correct answer by this formula—viz. $BW = 116 \text{ tons or } 116 \text{ tons safe load}$, taking the crushing weight of red deal at 3 tons. This weight, however, is rather more than Mr. Hodgkinson obtained by experiment, his figure being 5,748lb. (see Stoney on "Strains," art. 30). Taking this as a low result, we have a safe load of 10½ tons on the pillar. "Student" will find an example worked out in Stoney (art. 337), and checked by Rondelet's and Brereton's rules. I have worked out the above by one of Gordon's formulae, and the result is 10½ tons safe load. I may point out that Mr. R. J. Angel has left out a constituent of "C," which is crushing strength of the material per square inch \times sectional area of column (see Moresworth, 21st edition, p. 112). This was probably a clerical omission, as he works out the formula correctly. To obtain the diameter of a short column when the height and load are given, it is not possible to invert the formula given by "Student,"

because that needs correction. He must adopt "Sien Seng's" suggestion: assume a section, and calculate what it will bear until the right one is found. With regard to the girder formula, the one given is correct for a uniform distributed load and fixed ends. Occasionally one-sixth of the web is included in the bottom flange, but more generally it is omitted. On this question see Stoney on "Strains" (arts. 78, 100).—**DEPUTY B.E.**

[1888].—**House Drainage.**—The cesspool should certainly be ventilated, otherwise the carbon dioxide, sulphuretted hydrogen, or whatever form the sewer-gas may take, will, owing to their expansive properties, force the very best trap ever constructed. Moreover, if the cesspool is kept hermetically sealed for the period stated by your querist, carburetted hydrogen will be formed, owing to the decomposing matter, which gas is highly explosive if a light be applied. The ventilation of the cesspool should, however, be kept entirely separate from that of the drain. The 89th section of the Model By-laws requires "that each cesspool shall be provided with adequate means of ventilation." I enclose a sketch.—**R. J. ANGEL, Town Hall, Birkenhead.**

[1898].—**House Drainage.**—In all cases in sanitary systems it is essential to guard against any accumulation of gases by efficient ventilation. In the case in point, the circumstance of the cesspool being charged with gas would be a source of danger. Should the generation of gas reach such limits as to cause a pressure greater than that of the atmosphere, the trap would undoubtedly be forced, and even if the pressure did not reach such a point the water in the trap, especially if not frequently changed, would pass the gas through. The cesspool should most certainly be ventilated. I shall be pleased to give any further information on the subject.—**HARRY G. ASSITER.**

[1893].—**Floor Boarding—To Drive away Rats and Ants.**—In the trade 1½ flooring would be 1½in., 1 flooring would be 1½in., from the fact that 9in. deals and 2½in. battens, &c., lose a portion of their thickness in sawing and planing. Replying to "Subscriber" re rats, an infallible remedy is chloride of lime, as they flee from its odour as from a pestilence. Replying to "Bothered," to drive away red ants, place sprigs of ground-ivy where they are found.—**R. LOWE.**

[1899].—**Damp Walls.**—The best remedy for damp walls is to coat them with the patent solution, composed of silicate of soda and chloride of calcium in separate washes.—**R. J. ANGEL, Birkenhead.**

[1900].—**Stoneware Pipes.**—Stoneware and earthenware pipes are not made from the same clays. The clays from the Lias formation are mixed with powdered and calcined flint, and burnt in domed kilns. This produces stoneware. Earthenware articles are made from ordinary clays. Both are glazed in the same way with chloride of sodium.—**R. J. ANGEL, Birkenhead.**

CHIPS.

Mr. J. Passmore Edwards has, through Mr. W. C. Plant, chief librarian and clerk, handed over to the Shoreditch Library Commissioners the sum of £4,250, being the amount paid by them for the purchase of the library buildings, librarian's house, and a large plot of ground adjoining. By this munificence, and a further grant resolved upon last week by the City Parochial Foundation of the sum of £250, the Commissioners will be enabled to have two libraries instead of one for the densely-populated parish of St. Leonard's, Shoreditch.

Additions have recently been made to Redhill Cottage, Chislehurst, for Mr. C. C. Chapman, consisting of new servants' offices and outhouses, and additional sitting-room and bedrooms. The drainage and sanitary arrangements have also been entirely reconstructed. The work has been carried out by Mr. F. Wood, of Chislehurst, from the designs and under the direction of the architect, Mr. John Rawlinson, A.R.I.B.A., London.

The technical school committee of the Birmingham corporation have recommended to that body the acquisition of a freehold site for the proposed Central Technical School with a frontage in Suffolk-street, and extending rearwards to Summer-street, which can be purchased for £12,000. The land has an area of 2,762 square yards.

Good progress is being made with the building of the new technical schools at Aston. Mr. George H. Cox, of Birmingham, whose design was selected in competition in February last, is the architect, and Mr. F. N. Stephens, of that city, is the builder.

Legal.

SURRENDER OF TENANCY.

THE surrender of a lease should be by a deed in which the lessor accepts that surrender, and so the lease is properly and legally determined. But there can also be a surrender or determination of a lease or tenancy by operation of law, based upon the mutual consent of the parties, as shown by their acts. This frequently occurs when a tenant, desiring to get rid of a house for some reason or other, takes the key to his landlord. But, of course, this alone is not enough, and unless the landlord either expressly or impliedly accepts possession by keeping or using the key, there is no determination of the tenancy. The mere fact of a lessor or landlord allowing the key to remain in his possession will not of itself be conclusive, but if the landlord avails himself of the key to go into the house and repair it, or puts up a bill to let it, that will amount to such evidence of an intention on his part to determine the tenancy as to be practically conclusive against him.

In the recent case of "Smith v. Roberts" (*Times*, 17th November), these principles were applied to a curious state of facts. It appeared that the defendant was tenant of the upper rooms of a house in London for a term of five years from 1889. In 1890 notice was served on the defendant to repair a wall that was bulged, as being dangerous. This was sent to the plaintiff as owner. Ultimately a magistrate's order was made to do the work, and the plaintiff applied to the defendant for permission to send his men upon the premises for this purpose. The tenant answered that he could not prevent it, but would not consent, and should treat it as a disturbance, and he removed his furniture, and withdrew from possession, sending the key to the plaintiff, and stating that he determined the tenancy. The landlord replied, refusing to accept such a surrender of the holding, but he retained the key, sent his men to do the work ordered, did other repairs, and then offered the key back again. He now sued for a quarter's rent, as if the tenancy was still existing. The Judge who tried the case found for the defendant, and the Court of Appeal have just confirmed this ruling. They did this upon the conduct of the parties, and especially upon the facts that the plaintiff had really rendered the house uninhabitable, and had acted as if he agreed to determine the tenancy.

FRED. WETHERFIELD, Solicitor.

1, Gresham Buildings, Guildhall, E.C.

NOTE.—All questions for reply in this column must be headed "BUILDING NEWS," and must reach my offices, as above, by *Tuesday* morning to insure answer same week.

X. Y.—BUILDER.—EXTRAS.—CLAIM.—The builder can only claim for such extras as were authorised by the architect under the contract. But as the account of the building does not appear to be closed, his claim should be gone into, and settled upon this basis. If necessary the work so charged for should be measured up by the architect.

W.—BUILDER.—ARCHITECT.—PENALTIES.—The architect should prepare final certificate in the usual way when the works are quite completed, drawing the building owner's attention to the delay and the penalties incurred under the contract, and leaving him to enforce them if he thinks proper.

LEGAL INTELLIGENCE.

THE BUILDERS AND THE FLORIST.—Messrs. J. W. Wyatt and B. Corber, builders, sued W. G. Hodge, florist, of Plymouth, at the Devonport County Court last week for £20 balance due for work done. The plaintiffs contracted to erect two greenhouses at Crown Hill in April last for £184, and in accordance with a stipulation the contracts were mulcted of £20 for four weeks which they were delayed after the arranged date of completion. The action arose out of the allegations that defendant delayed them a week in starting operations, and the further hindrance was occasioned by Mr. Hodge entering into a separate contract with a Mr. Wyatt to do some work to the houses. Defendant denied these pleas, and affirmed that he had to throw away £30 worth of cucumber plants in consequence of the non-completion of the works. His Honour reserved judgment.

UNFENCED MACHINERY.—Messrs. Wm. Thomas and Co., builders, of Cardiff and Pontypridd, were summoned at the Pontypridd Police-court on November 23rd by Mr. Augustus Lewis, H.M. Inspector of factories, for having neglected to properly fence a flywheel upon their works at Pontypridd. Mr. Thomas said that, owing to a

change of foremen, his attention was never called to the matter until the 1st of November, when the fencing was at once put up. The defendant was ordered to pay the costs of the case.—A similar charge was preferred against Mr. John Henry James, builder, Berw-road, Pontypridd, at whose works a boy had been killed. Defendant was fined £1 and costs.

RE J. G. ROGERS.—This case, that of a builder, of Timpson-road, Landport, and formerly a member of the Portsmouth Town Council, had been adjourned for the production of a trading account. The Official Receiver said, at the hearing on the 19th Nov., the accounts submitted to him were unsatisfactory. They were inaccurate, and made on a wrong basis; but if taken as they stood, the accounts showed a deficiency of £2,000, instead of a surplus of £4,000. Under those circumstances, he must ask for amended accounts, and should adjourn the case until Dec. 19.

IN RE GEORGE NEWMAN AND CO. (LIMITED).—Mr. Buckley, Q.C., appeared before Mr. Justice Wilkins, on Friday, on behalf of Mr. C. J. Steward, official receiver and provisional liquidator of the London and General Bank (Limited), (now in liquidation), in support of a petition by the bank, as creditors, in respect of about £90,000, for a compulsory winding-up order. The company were builders and contractors, and had been brought down by the fall of the Liberator Building Society. No opposition was offered, and the Judge made the usual winding-up order.

CONVICTION OF A BANKRUPT BUILDER.—Frederick Banyard, better known in Sussex as Frederick Stevens, builder and contractor, of East Grinstead, surrendered to his bail at the Central Criminal Court, on Friday, on a charge of removing and concealing large quantities of property belonging to the trustees of his bankruptcy when a member of the firm of Pearse and Banyard, at Kensal-green, in April, 1892. The prisoner failed again recently at East Grinstead, in connection with the collapse of Head's Bank, and his examination in connection with this affair led to his identification as Banyard, and to the disclosure of the facts of the proceedings of more than ten years ago. The jury returned a verdict of guilty, and prisoner was sentenced to two months' imprisonment.

AN ARBITRATOR'S AWARD UPHOLD.—In the Chancery Division on Tuesday Mr. Justice Romer heard arguments in a dispute between the Conservators of the Thames and the London, Tilbury, and Southend Railway Company. When the Railway Company required land for a station at Thames Haven, in the parish of Fobbing, Mr. Littler, Q.C., was chosen arbitrator, to decide the amount to be paid to the Conservators, and in December, 1890, he awarded £2,158. The Railway Company endeavoured to set aside this award, on the ground that it was made upon a wrong basis—that of the Thames Conservancy Acts in lieu of the Lands Clauses Consolidation Act. But the Judge held that it could not be impeached, and decreed specific performance.

THE MODEL WINDMILL SKY-SIGN CASE.—The London County Council and Messrs. Carwardine and Co. appeared at the Worship-street Police-court on Wednesday last for a readjudication of a summons taken out by the Council against Messrs. Carwardine for keeping and maintaining a certain erection over and above their premises—viz., a model windmill—the same being a sky-sign within the meaning of the Act. The whole question was argued before this Court last spring, when Mr. Rose dismissed the summons, deciding that the structure was not within the Act. On appeal by the Council, however, to the High Court, the case was ordered to be reconsidered by the magistrate, and hence the reappearance of the parties. It was now said that the letters had been removed, and the advertisement painted out. Whether the erection was to be demolished is to be a matter for further argument, Mr. Burton applying for further summonses against Messrs. Carwardine. Mr. Rose imposed a fine of 20s., no costs being allowed.

AN ARCHITECT CONVICTED OF ASSAULT.—On Saturday, at the Dorking Bench, William J. Shearburn, architect and surveyor, Dorking, was summoned for assaulting and beating Arthur Reigate. Complainant, a butcher, struck the defendant's dog for chasing sheep he was driving, whereupon defendant snatched the stick away and gave the complainant three or four sharp blows. He was ordered to pay a fine of £3 and costs, 14s. 6d.

ARBITRATION AS TO MAIN ROAD MAINTENANCE.—Mr. Thomas Codrington, C.E., an inspector of the Local Government Board, attended at the Municipal Offices, Burton-on-Trent, the other day, for the purpose of arbitrating upon the difference which had arisen between the Burton Town Council and the Staffordshire County Council as to the amount of expenses which should be paid by the County Council for the repair of the main roads for the year which ended March, 1890. The County Council had paid £1,500 on account, and the question was to what extent they ought to be called upon to contribute towards the watering, scavenging, and repair of the main roads, which,

in fact, are the old turnpike roads. The Town Council called as witnesses the borough surveyor (Mr. Swindlehurst), Mr. Hooley (county surveyor of Nottinghamshire), Mr. Eayrs (surveyor of West Bromwich), and Mr. Harley (who formerly had the management of the Staffordshire roads). On the other side the only witness called was Mr. Moncur (chief road surveyor to the County Council). After a full investigation, the case terminated, and Mr. Codrington will make his report to the Local Government Board.

INFRINGEMENT OF BY-LAWS.—At the Wallasey petty sessions on the 16th ult., George Robinson, builder, Massey Park, Liscard, was summoned by the Wallasey Local Board for having contravened the building by-laws by erecting a house more than two stories high, the walls of which were less than 14in. thick. For the prosecution it was stated that the plans indicated a building of two stories; but the manner in which it was built made it one of three stories, what was originally intended for a bathroom having been made into a bedroom. Evidence was given by Mr. Salmon, surveyor to the board, and the Bench imposed a penalty of 40s. and 11s. 6d. costs.

IN RE W. R. PARKER, CARDIFF.—The first meeting of the creditors of Mr. Councillor W. R. Parker, contractor, of Station Approach, Cardiff, and Marine Parade, Penarth, was held at the office of the Official Receiver in Bankruptcy on Thursday in last week. In regard to the estate of W. R. Parker and Co., the statement showed unsecured liabilities, £7,994 3s. 2d.; partially secured creditors expected to rank against them £2,351 14s. 9d.; making the total liabilities to £10,345 17s. 11d. The assets, after deducting for preferential creditors, were £3,536 10s. 6d. and left a deficiency of £4,979 6s. 4d. The surplus, after payment of the personal estate, will go to the credit of the preferential claims under the partnership estate. With regard to Mr. Pedrette, there was a deficiency of £1,132 14s. 11d., and the liabilities amounted to £1,700. The debtors offer a composition of 7s. 6d. in the pound, payable as follows:—4s. within six months hence, and 3s. 6d. within twelve months. No security was offered. Several creditors thought an offer of 10s. should have been made, and after much discussion the meeting was adjourned to enable him to submit a fully-secured offer of composition.

RE A. E. WARD.—Alfred Ernest Ward, of Eccles New-road, Weaste, builder, underwent his public examination at the Salford Bankruptcy Court on Monday. The bankrupt's statement of affairs showed liabilities to unsecured creditors £1,098, and contingent or other liabilities £40, making a total of £1,138, and assets nil. The bankrupt alleged as the cause of his failure "transferring his property to another person, who promised that all debts should be paid; also contracting debts for other parts of a speculation into which he had entered, being all the while promised that everything should be paid." In January, 1891, the bankrupt, with three other persons, embarked in a building speculation, and became joint purchasers of 28 houses, and 11,000 or 12,000 yards of land at Weaste. In July, 1891, bankrupt and the other parties to the speculation dissolved partnership, and he took over the property and the liability. All his present liabilities, he said, arose out of the partnership. The examination was adjourned to the 19th December, the bankrupt being directed to furnish amended accounts.

CURIOUS ACTION BY AN ARCHITECT-AND-CONTRACTOR.—At the Llandudno County-court last week, Edwin Turner, architect, sued William McGrath, of Llandudno, and late of Birmingham, for £25 for professional services. The plaintiff, it was stated, had been an architect in Llandudno for the past 20 years, and the defendant was a stranger who had come into Llandudno some time ago and built a house, which he did not like. He saw plaintiff, who showed him over the house of Mr. T. T. Marks, the former surveyor to the local authority, and defendant agreed to the building of a house of the kind with certain modifications. He then instructed Mr. Turner to draw out plans and specifications. These plans were submitted on two or three occasions, and there was some conversation about cutting down the expenses. Mr. Turner then offered to build the house for £1,300. This was agreed to, and Mr. Turner communicated with a Robert Roberts to sublet him the masonry. The sum of £80 had been set aside for chimneys and mantelpieces. The plaintiff said he would have the grates and mantelpieces from the wholesale house he dealt with, because he had based his estimate for the work upon the idea that he would get the little profit of the trade by way of discount. The defendant said "Oh! those grates will be supplied from my own firm in Manchester. I am entitled to the discount." Mr. Turner insisted upon having the discount. Thereupon the defendant left, and they did not have any transaction together after that. The plaintiff was called and confirmed counsel's opening statement. First of all, the cost was not to exceed £1,250, and

£60 was set for grates and chimneys. Ultimately the defendant got another person to finish the house, which had cost him double the money. Cross-examined, witness said he had Mr. Marks' house in his mind as being one which would be suitable for Mr. McGrath. Witness sold the house to Mr. Marks for £1,300, and he supposed it cost a little less than that to build. Witness said that at first he was architect, and after a time he became contractor, having told defendant he would build the house. If he had gone on with the contract he would simply get £1,300, and on that he would have had his profit. His Honour said the question was, whether the position of architect at first occupied by the plaintiff became merged in the contractor. He was an architect at first, but elected to become a contractor, and he could not go back to his old position. Mr. T. T. Marks, C.E., was called and asked what was the custom regarding the purchase of grates and mantel-pieces for new houses. The witness said he had never been in that position, and therefore could not answer. If he was a contractor, he would try to get the purchase of the articles so as to have the discount, but as an architect he would have nothing to do with it. His Honour: If the plaintiff had stuck to the original rôle of architect, he would have been entitled to his fee. Mr. Porter argued that the plaintiff made no plans, and that they were simply copies of those of Mr. Marks' house. Wm. McGrath, the defendant, spoke as to the negotiations which took place between him and the plaintiff, who volunteered to build him a house. He looked upon Mr. Turner as a contractor pure and simple. The house had been built from other plans, and placed in a different position on the field. His Honour said it was evident that the plaintiff started as architect, but when he undertook to build the house, from that moment he became the contractor. It was practically giving up his right as architect, and then he could not come on as before. Whether he was contractor from the first, or became contractor afterwards, the original position of architect had been broken, and undoubtedly he could not hark back into the position of pure architect. Mr. Turner's character as contractor predominated over that of architect. There would be judgment for the defendant.

EXEMPTIONS UNDER THE BUILDING ACT.—The secretary of the Regents' Canal and Railway Company was summoned before Mr. Horace Smith at Clerkenwell under the Dangerous Structures clauses of the Building Act, 18 and 19 Victoria cap. 122. The solicitor to the London County Council called Mr. Henry Lovegrove, district surveyor, to prove his certificate as to the condition of an ancient timber building in Graham-street, City-road, and, after hearing arguments by a solicitor on behalf of the company, decided that the Canal Company was not exempted by the third section of the Act, and the case was adjourned for 28 days to give time for the removal of the building. Another summons was then heard, taken out by Mr. H. Lovegrove, against the Canal Company, for erecting a building without giving notice. The district surveyor stated that the building in question was occupied by a firm of woodchoppers, and was not only erected without notice, but was irregular. The magistrate decided that the exemption clause did not apply, and fined the company £1, with costs £1 3s. The solicitor to the Canal Company asked the magistrate to state a case.

A new Masonic Hall at Moffat, N.B., was opened last week. It is plain Grecian in style, and has been reconstructed from plans by Mr. F. I. G. Carruthers, P.G. Architect of Dumfriesshire.

St. Luke's parish church, Prestonville, Brighton, is being heated by a hot-water system (low-pressure). The contractor is Mr. John F. Phillips, of Richmond-buildings, Brighton. The work is being superintended by Mr. C. E. Hewitt, surveyor, of Prestonville, Brighton. In removing the old furnace, it was found that a part of a 6in. iron flue-pipe, about 18in. in length, was completely destroyed, and that the floor above (which is a wooden one covered with tiles) was considerably charred. The wonder is that no fire took place, as the naked pipe was only about 1ft. from the joists. An iron church on the same site was burned down about the year 1870.

A very large Cambridge-quarter clock, showing the time on four external mosaic dials, 11ft. each in diameter, and striking the hours and quarters upon five bells of the total weight of 5 tons 1qr. 10lb., with dropping arrangement, and Lord Grimthorpe's double, three-legged gravity escapement, 1½sec. compensation pendulum, with cylindrical-shape bob weighing 450lb., and all the latest improvements, has been presented to the city of Liverpool, and fixed in the Jubilee tower of the Liverpool University College, and was set going by the donor on the 15th November. The clock also drives three large dials inside the building by an electrical arrangement attached to the clock movement, and the whole were supplied and fixed by Wm. Potts and Sons, of Leeds.

WATER SUPPLY AND SANITARY MATTERS.

BRUTON WATER SUPPLY.—The Wincanton Rural Sanitary Authority have had under their consideration a scheme by Mr. A. P. J. Cotterell, A.M.I.C.E., of Bristol, for the supply of water to the town of Bruton, Somerset, and, after consideration, have given instructions to proceed with the necessary plans. The water will be obtained from two springs, one of which will supply the eastern, and the other the western portion of the town. Both springs come from the lower oolitic formation. Covered service reservoirs will be placed near the springs, and the water will gravitate thence into cast-iron distribution mains to all portions of the town. The eastern and western service pipes will be connected so as to increase the pressure in the western portion in case of fire.

EVESHAM SEWAGE WORKS.—A Local Government inquiry was held on the 11th ult. at the Town Hall, Evesham, by Mr. Herbert Tulloch, A.M.Inst.C.E., for sanction to raise a loan for sewage purification purposes. The Mayor and several leading members were in attendance, and Mr. R. Mawson, C.E., borough engineer, stated that the council had decided to adopt the International system of ferrocene and polarize in order to prevent pollution of the Stratford Avon. Mr. F. Candy, of Westminster, gave technical evidence as to the system to be used. There was no opposition, and it is probable that the works will be carried out without delay.

KEYNSHAM, SOMERSET.—The Keynsham Rural Sanitary Authority have instructed Mr. A. P. J. Cotterell, C.E., of Bristol, to prepare a scheme for the sewerage and sewage disposal of the town of Keynsham, near Bristol.

TORQUAY.—Torquay has admittedly one of the best water supplies of any town in England, both for quality and quantity. Yet it has been awkward for St. Raphael's Convalescent Home, which being two miles distant from the local storage reservoir, and practically on the same level, great inconvenience has been experienced thereby. The lady superior, very soon after taking up her abode as superintendent, had a scheme submitted to her, whereby she could do away with the very objectionable lift pumps, &c. To form a storage a large cast-iron tank, the capacity of which is 12,000 gallons, has been erected upon a unique two-story brick building, and resting upon steel joists, at such height so as to gravitate over the whole of the vast premises, which occupy some 16 or 18 acres. To supply the tank a 3in. cast-iron pipe, coated with Angus Smith's solution, is carried away through the streets to about a mile and a half distant and connected with a stand-pipe, which has its supply direct from the large Totteford reservoir eighteen miles away. The work has been carried out by the firm of William A. Gass, Torquay, engineer and contractor; Mr. C. E. Robinson, who has constructed several cliff lifts, being the consulting engineer.

POLLUTION OF THE YEO.—The Wincanton Rural Sanitary Authority have been threatened with an action for alleged pollution of the Yeo near its source by the discharge of sewage from the town of Milborne Port without proper treatment, called in Mr. A. P. J. Cotterell, C.E., of Bristol, to advise them upon a better system of disposal. His report was considered by a vestry meeting at Milborne Port, and was unanimously passed, and having since received the approval of the sanitary authority, instructions have been given to proceed. The sewage will be treated with ferrocene just before reaching the existing outfall tanks, whence, after deposit, the effluent will be carried in pipes to the Henover Meadows. Here 16 acres of ground will be prepared for irrigation, the ground being deep ploughed, and the surface formed into panes, or divisions, for intermittent filtration, and the purified water will thence be conveyed to the stream.

The Runcorn Board of Improvement Commissioners decided on Monday to build public baths for the town. It is proposed to erect the baths on land adjoining the town hall in Waterloo-road, and at the rear of the projected Technical Institute; and the plans drawn by Mr. Barker, the board's surveyor, show a building having a plunge bath about 60ft. long, and six private baths. Northwich Baths have been taken as a model, and the estimated cost is £3,000.

Mr. Justice Wills gave judgment on Saturday in an action brought by the Gas Light and Coke Company against the Metropolitan Railway Company, to test the right of the former to cut through the piers which support the railway bridges in order to lay their mains. An agreement was come to between the parties seven years ago under which this was allowed; but the railway company now desired this agreement to be rescinded, alleging that it was entered into by mistake. This, however, the Judge refused to do; but on other points gave decision in favour of the railway company.

Our Office Table.

A new school for the study of the civilisation of Ancient Egypt is being provided for London from the bequest of the late Miss Amelia Edwards, the well-known Egyptologist, who founded by her will a Chair of Egyptology in University College, the first endowment of the kind in this country. The council of the college have appointed Mr. W. M. Flinders Petrie to be the first Edwards Professor, and he will commence work early in the new year. The appliances for study will include a library complete in works of reference for the History, Language, and Antiquities of Egypt, and upwards of a thousand photographs of monuments, with paper impressions of inscriptions. In addition to the typical collection of Egyptian antiquities bequeathed to the college by Miss Edwards, Professor Petrie hopes to obtain the temporary loan of some valuable private collections. The scheme of operations is:—(1) Lectures on current discoveries, on history, and on the systematic study of Egyptian antiquities. (2) Lessons on the language and philology of Egypt. (3) Attendance in the library on fixed days for the assistance and direction of students working there. (4) Practical training on excavations in Egypt.

The total number of private Bills to be introduced in the House of Commons next session relating to or affecting England and Wales is 152. Of this number 41 are promoted by corporations, county councils, and other public bodies. Fifty-nine Bills relate to docks and railways and 20 gas and water undertakings, and of the remaining 32 some relate to tramways, piers, harbours, canals, bridges, electric lighting, and others are Bills promoted by companies for power to amend their articles of association. Of the total number of Bills 23 relate directly to or will contain powers affecting London, of which number the London County Council are responsible for five Bills of an important character.

An American contemporary, the *Engineering News*, gives a simplified formula to ascertain the safe load for bearing piles implanted in soft soil, where the pile never refuses to go further so long as the blows are continuous. The proposed formula consists in the equation $L = \frac{2wh}{s+1}$, in which

L is the safe load, w the weight of the hammer, h the fall of the hammer in feet, and s the "set," or small sinking of the pile at the last blow. L will be expressed in the same terms, whether tons, pounds, or kilograms, as w .

The Vicar of Arundel appeals for £1,000 for re-roofing the nave of his fine parish church. The circumstances are unusual. Most of the present roof was erected some eighteen years ago during the restoration by the late Sir Gilbert Scott, and according to the report of Sir Arthur Blomfield, there are no faulty timbers, or want of proper ventilation, the mischief solely arising from the ravages of the grub known as *Anobium tessellatum*, which bored its way from the old wood to the new portions then inserted. The only remedy is to strip the whole roof and examine every beam and board. The roof must therefore be overhauled and reconstructed without delay, and regardless of cost, as there are obvious risks lest the grubs should find their way into the seats and other woodwork of the church, and as the venerable Bishop of Chichester observes in his commendation of the appeal: "The peculiar circumstances of Arundel greatly increase the difficulty of obtaining the necessary funds for this indispensable work."

At Carpenters' Hall, London-wall, Professor Banister Fletcher, F.R.I.B.A., M.S.A., delivered a lecture on Friday on "Sanitary Building Construction." Health, he pointed out, was of the first importance if we were to enjoy life and happiness. And to secure health we must live in good houses. At the very outset, it would be well to avoid faddists who were in the habit of stating that, unless the latest approved article were used, houses could not be in a sanitary condition. This, of course, was simply fadism. At the same time, it was always necessary to have approved materials. Beginning at the foundation, Professor Banister Fletcher went on to remark that the best soil was gravel. When houses were put up on mere dust, composed of oyster shells, &c., dry rot would soon be visible

the building. The foundation, which was of the utmost importance, was next dwelt upon at great length. The site was then touched upon, the speaker, in conclusion, referring to the various matters to be borne in mind in connection with the erection of a thoroughly sanitary building.

THE Highgate Museum of Sanitary Appliances will be opened by the Lord Mayor of London on the 8th December. This museum contains a valuable and instructive collection of modern sanitary appliances. It has been established by the Hornsey local board, who, some two years ago, conceived the idea of bringing together a few specimens of the most improved fittings for the guidance of builders and others engaged in their district. With this object in view, a room with floor-space of 940ft. super. was erected, and manufacturers were invited to submit specimens of their sanitary goods. In order, however, to ensure the permanency of the museum, it was stipulated that all articles deposited should become the property of the board. The advertising element has been most carefully excluded. The principal manufacturers responded to the invitation, and it soon became necessary to provide more accommodation. The museum now consists of seven rooms, having a total floor-space of 4,900ft., and there are upwards of 1,000 exhibits. Accommodation has been provided for the instruction of plumbers, and in conjunction with the Worshipful Company of Plumbers and the Middlesex County Council, the board are making arrangements for holding classes in plumbing under the direction of skilled teachers. It is also intended to inaugurate courses of instruction in sanitary science—a rudimentary course for women, and a more practical course for builders, artisans, and others.

THE annual report of the borough surveyor for Walsall states that plans for 572 new buildings were approved in the year, as against totals of 199, 591, and 546 in the three previous years. Among the public works and improvements carried out are the erection of a public mortuary at Wolverhampton-street wharf, alterations and additions to the wharf, the laying down of the equipment for the electric tramways, and the erection of a generating station, the completion of the Free Library and Art Gallery, an improvement in the building lines of the Square and Digbeth, a part of the site of the old Woolpack Inn having been taken in; the purchase of a considerable part of the land required for the new cemetery at Coalpool, the addition of a strip of land to the road in Sandwell-street, and improvement at the corner of Pleck-road and Wolverhampton-road, the addition of piece of land to the road in Profit-street, and the widening of the road, the widening and remaking of Windmill-lane, and the straightening and widening of the mill stream between Tasker-street and Corporation-street. The Arboretum was extended and laid out, and at Reed's Wood much levelling was done as relief works.

AN Arts and Crafts Exhibition, containing an interesting collection of useful and ornamental articles of manufacture, has been opened in York-street Skating Rink, Sydney, under the auspices of the Sydney Architectural Association. It was opened by the Governor of New South Wales on the 2nd Nov., when the annual conversation of the association was given by Mr. Hurst Seager, the President, and the committee. Architectural drawings by Sydney, Melbourne, and Brisbane architects were hung, and the city board of water supply and sewerage made a display of sanitary appliances, while examples of gas and electric lighting and fitting, wood-carving, and many building appliances were on view. The exhibition was a novelty in Australia, and has been very successful.

AN election of one male pensioner on the funds of the Builders' Benevolent Institution was held at the offices, 35, Southampton-row, Bloomsbury-square, on the 24th ult. The result of the polling was as follows: Joseph Lestock Mould, aged 70, of 60, Muriel-street, Islington, builder (second application), 697 votes; John George Bishop, aged 65, of 21, Spencer-square, Ramsgate, builder (first application), 2,272 votes, including 250 votes in respect of his subscriptions to the institution. The successful candidate was, therefore, declared to be John George Bishop. The votes given to the female applicants were as follows: Sarah Elizabeth Drake, aged 60, Tilers' and Bricklayers' Almshouses, King Henry's-walk,

Balls Pond, widow of Francis Drake, late of Acton, builder (fourth application), 2,383 votes; Susanna Mansell, aged 68, of 20, Bridge-road, Hammersmith, widow of William Mansell, late of Hammersmith, builder (third application), 2,484 votes; and Mary Ann Healing, aged 62, of Curtain-road, Shoreditch, widow of Samuel Thomas Healing, late of Spitalfields, builder (second application), 189 votes.

A SPECIAL general meeting of the Builders' Clerks' Benevolent Institution, convened by advertisement, was held on Tuesday evening, November 29, at the offices, 21, New Bridge-street, E.C., for the purpose of electing a pensioner on the relief fund. Mr. Colin G. Patrick, who presided, gave some particulars of the case, after which the applicant, Mrs. S. M. Enright, was duly elected by show of hands, being the only candidate. Mrs. Enright is the thirty-fifth pensioner elected since the foundation of the Institution.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Royal Institute of British Architects. "Some Problems of Town and City Developments," by Wm. C. Street. 8 p.m.
Surveyors' Institution. 8 p.m.
Society of Arts. Cantor Lecture No. III., "Generation of Light from Coal-Gas," by Prof. Vivian Lewes. 8 p.m.
Liverpool Architectural Society. "Bricks and Brickwork," by John Slater, B.A., F.R.I.B.A. 6.30 p.m.
Leeds and Yorkshire Architectural Society. "Vaulting," by A. Keen. 7.30 p.m.
TUESDAY.—Institution of Civil Engineers. Discussion on "The Manufacture of Small Arms." 8 p.m.
WEDNESDAY.—Society of Arts. "The Chicago Exhibition," by James Dredge. 8 p.m.
FRIDAY.—A.A. Lyric Club. Concert at the Mona Hotel, Henrietta-street, Covent Garden. 8 p.m.

The Architectural Association.—December 2nd. Third Ordinary General Meeting to-night (Friday) at 7.30 p.m. Paper by John Brett, Esq., A.E.A., on "Daylight in the Dwelling-House."

ERNEST S. GALE Hon. Secs.
F. T. W. GOLDSMITH

CHIPS.

A bronze cast of Mrs. Guild's portrait bust of Mr. G. F. Watts, R.A., has been given by Mr. William Agnew to the Whitworth Institute at Manchester.

St. Simon's Church, Bethnal Green, has just been reopened after repair and restoration. Messrs. W. Rhind and Son, of Fulham-road, S.W., carried out the work.

The peal of eight bells in the parish church of Bury, Lancs, has been re-rung, after having been hung afresh, re-tuned, and in two cases recast. Messrs. Taylor and Co., of Loughborough, carried out the works.

The name of Mr. George Owen, of Oswestry, engineer of the Cambrian railways, has been placed upon the Commission of the Peace for the county of Salop.

On Wednesday a reredos, entirely of alabaster, designed by Mr. E. J. Tait, architect, of Exeter, was dedicated in the church of Bratton St. Mary, near Clovelly.

The directors of the London, Tilbury, and Southend Railway intend to finish the new line from Tilbury Docks to Romford by June next.

The foundation-stone of Kirkwall Free Church was laid on Monday by Mr. Stephen Muir, the oldest member of the session. The church, which is to accommodate 600 sitters, is estimated to cost £1,800.

The Special Committee of the Sheffield Town Council appointed to carry out a resolution recently come to for the widening of High-street, the main thoroughfare of the town, at an estimated cost of £263,000, have negotiated agreements for the purchase of nine out of eighteen properties required. These agreements will enable a commencement to be made with one of the most important street improvements in the history of Sheffield. The new street will be 80ft. in width.

At a mechanics' meeting held at Stockport last week it was decided to form a building trades' federation for the town and district, consisting of representatives of all branches of the trades.

A school at Calderbank was formally opened on Monday by the School Board of Old Monkland, N.B. The building accommodates 450 scholars at a cost of £2,700.

The German church in Bellevue, Edinburgh, has been reopened this week, after having been decorated by Messrs. G. Dobie and Son, of that city.

Trade News.

WAGES MOVEMENTS.

BIRMINGHAM.—A meeting of the Builders' Labourers' Branch of the National Union of Gas-workers and General Labourers was held at Bristol-street schools, Birmingham, on Friday evening, to consider the notice received from the master builders for a reduction in wages. It was unanimously resolved to send a counter-notice for an increase in wages of one halfpenny per hour, and an alteration of the working rules.—The Birmingham branches of the Operative Bricklayers' Society held a dinner at the Colonnade Hotel in that city on Tuesday night, for the purpose of presenting to Mr. T. M. Colmore (Stipendiary) an illuminated address in recognition of the services he rendered to the trade during the recent dispute. Mr. F. Freeman presided. Alderman Cook presented to Mr. Colmore an address conveying to him the thanks of the bricklayers for his services as mediator in the dispute which took place in the spring and summer. Alderman Cook said that the dispute in the building trade caused a considerable amount of irritation, and the termination of that dispute was due to the mediation of Mr. Colmore. Mr. J. Freeman proposed "The Birmingham Master Builders' Association," to which Mr. C. H. Barnsley responded.

DORCHESTER.—The important extension works in progress at the Dorset County Asylum have been stopped owing to a dispute between Messrs. Pethick Bros., the contractors, of Plymouth, and the bricklayers and carpenters. The amount of the contract is £60,000, and nearly 200 men are engaged on the work. The men refused to continue work on Saturday, a proposal of the contractor to reduce the working time by one hour per day during the winter months being the cause of the difference.

LEEDS.—The dispute between Messrs. Obank and Sons, the contractors engaged in the erection of the new Post-office at Leeds, and a section of their workmen, was, after lasting for over six weeks, brought to a satisfactory termination on Friday, by the intervention of the Leeds Board of Conciliation and Arbitration. By the settlement it is provided that in future no engineman shall be employed at the Post-office building in doing work usually performed by labourers. It was agreed that the works should be open until noon on Monday next, Dec. 5, for the return of such of the old hands as chose to avail themselves of the opportunity of going back, and for whom employment can be found. After that time the employers are to be at liberty to engage whom they think fit.

The adjudications in bankruptcy announced in Tuesday's *Gazette* include the name of Walter Sheridan Peckover, of Birmingham, architect.

Mr. Louis Fagan, Assistant-Keeper of the Prints, British Museum, is about to retire, owing to ill-health, from the post which he has held during the last twenty-four years.

The new temporary hospital, Otley, is being warmed and ventilated by means of Shorland's patent Manchester stoves, the same being supplied by Mr. E. H. Shorland, of Manchester.

The Earl of Derby has offered to contribute another £500 towards the completion of the Manchester Cathedral. The whole of the work, including several more stained-glass windows promised, will be completed before Easter next. The entire amount expended has been about £80,000, and Mr. J. S. Crowther, of Manchester, has been the architect.

In celebration of the marriage of Mr. John White, C.E., the Borough Engineer of Folkestone, the staff of employees in the service of the corporation presented that official on Tuesday week with a souvenir, in the shape of a marble timepiece. On that evening the entire staff, to the number of about 130, were entertained to a meat tea at the upper store in the corporation yard by Mr. and Mrs. White.

The Okehampton Rural Sanitary Authority having applied to the Local Government Board for sanction to borrow £2,500 for works of sewerage, sewage disposal and water supply for the village of Hatherleigh, Mr. Samuel J. Smith, C.E., held an inquiry into the subject matter of the application at the Assembly Rooms, Hatherleigh, last week. Mr. Appleton, C.E., the engineer for the proposed works, produced and explained the plans.

Mr. William Eve, F.S.I., having completed 21 years as representative of Stoke Newington parish at the Board of Works for the Hackney district, has been presented by his colleagues, at a dinner at the Holborn Restaurant, with a handsome silver tea and coffee service, as evidence of their appreciation of the valuable services he had rendered to the parishes during that period, for the past 14 years of which he has been chairman of the General Purposes Committee.

STAINED GLASS.

GLASGOW.—A stained-glass window is about to be erected in St. Andrew's Church, Glasgow, in memory of the late Robert Anderson, letterpress printer. The window has been executed by Messrs. Stephen Adam and Co. The design is based on the words of the Psalmist, "God hath anointed thee with the oil of gladness above thy fellows." As interpreting the text, the central part of the window is filled with angel-figures, typical of praise and rejoicing, with harp and lute. These figures are treated after the manner of Early Florentine mosaic work. In the upper part of the window is a free treatment of cherubic figures, scrolls, flowers, &c., while at the base is the inscription.

CHIPS.

The concluding sale of the Egremont collection of old masters fetched very poor prices when offered by Christie's on Saturday. The whole series of 134 pictures, chiefly by and after the old masters, only brought £2,324—the only prices worth noting being "The Entombment," by Albertinelli, 295 guineas; "The Betrayal of Christ," said to be by Vandyc, 810 guineas; and "The Rape of Europa," by P. Veronese, 195 guineas.

Before Lords Justices Lindley, Bowen, and A. L. Smith, on Friday, an appeal was heard by the Barry Railway Company against an order of Mr. Justice Kekewich, restraining the company from proceeding with a reference to the arbitration of their engineer of a dispute which had arisen between them and Mr. Jackson, the contractor for works they are constructing at the Barry Dock. The Court, by a majority, allowed the appeal, and discharged the injunction, Lord Justice A. L. Smith dissenting.

The theatre at Lincoln, an old building which had been frequently renovated and partially reconstructed to meet modern requirements, was destroyed by fire on Saturday. The damage amounts to about £3,000.

A monument is to be erected to the late Cardinal Lavigerie at Carthage. Signor Anderlini, the Roman sculptor, has been charged to execute the work.

The Clitheroe Town Council decided on Friday to apply for powers to borrow £20,450 for the construction of sewerage for the borough. Up to the present the town has not had any proper sewerage scheme.

The foundation-stone of the new Higher Grade School for Wolverhampton was laid last week. Mr. T. H. Fleeming, of that town, is the architect, and Mr. Henry Lovatt, also of Wolverhampton, is the contractor.

The bridge which carries the Midland Railway across the Avon just outside Bath Station is being reconstructed after 23 years' use. On Saturday the contractors, Messrs. Handyside and Co., of Derby, commenced operations on the arrival side of the bridge, and this is expected to be renewed in ten days. The other portion will not be dealt with until after Christmas. Relays of men work night and day on the job, electric lights being provided. The work is under the supervision of Mr. Meredyth, district engineer, Gloucester.

St. Peter's Hall, Church-street, Liverpool, was completely destroyed by fire on Sunday. The hall was formerly the home of the Liverpool Academy, and was the scene of many annual exhibitions of pictures. It was afterwards used chiefly for bazaars and public meetings, but latterly has been used as a billiard-room.

The Wesleyans have opened a new chapel at Wolverton, which has cost £2,500, another at Bideford, which has cost, with the site, £6,000, and a third at Upton Park, East Ham, which has cost £4,000.

At a special general meeting of the Royal Anglo-Australian Society of Artists, held on Tuesday, the following artists were duly elected members—viz., Colin B. Phillip, R.W.S.; F. W. W. Topham, R.I.; W. B. Wollen, R.I.; W. W. May, R.I.; Sutton Palmer, R.B.A.; G. C. Haité, and Allan Hook.

Holloway's Pills.—This Medicine has resisted every test which prejudice and vested interest could impose upon it. As alternatives, aperients, and tonics these Pills have no equal. To every aged and delicate person whose appetite is defective, digestion infirm, and tone of health low, this medicine will be a precious boon, conferring both ease and strength.

CRAIGLEITH STONE.

FOR STAIRCASES, STEPS, & LANDINGS.
VERY HARD, and NEVER WEARS SLIPPERY.

Apply to **J. & A. CREW,**

Cumberland Market, London, N.W.

Messrs. CREW have a Large Stock on their Wharves for Selection.
Telegrams—"CRAIGLEITH, LONDON."

BILLS OF QUANTITIES & PLANS.

T. PETTITT and CO. Lithograph Bills of Quantities with the greatest expedition. Accurately copied from the draft in clear hand. Orders from the country returned by evening mail on the same day. Terms on application. Also Plans of Building Estates and General Plan Work at very reduced prices.—T. PETTITT and CO., Lithographers, 28, Fritch-street, Soho, London, W. Established 60 years.

DOULTING FREESTONE.

THE CHELYNCH STONE—The Stone from these Quarries is known as the "Weather Bed," and is of a very crystalline nature, and undoubtedly one of the most durable Stones in England.

THE BRAMBLE DITCH STONE is of the same crystalline nature as the Chelynych Stone, but finer in texture and more suitable for fine moulded work.

Prices, and every information given, on application to **CHARLES TRASK and SONS**, Doulting, Shepton Mallet, Somerset. London Agent:—Mr. E. A. WILLIAMS, 16, Craven-street, Strand, W.

HAM HILL STONE.

The attention of Architects is specially invited to the Durability and beautiful Colour of this material.
Quarries Well Opened; Quick Despatch Guaranteed; Stonework Delivered and Fixed Complete. Samples and Estimates Free.

Address:—

THE HAM HILL STONE COMPANY,
MORTON, STOKE-UNDER-HAM, SOMERSET.
London Agent:—
Mr. E. A. WILLIAMS, 16, Craven-street, Strand W.C.

WM. OLIVER & SONS,

TEAK, VENEER, and FANCYWOOD
MERCHANTS,
20, BUNHILL ROW, LONDON, E.C.

The most extensive Stock of every kind of
Wood in Planks and Boards, dry and fit for
immediate use.

TENDERS.

Correspondents would in all cases oblige by giving the addresses of the parties tendering—at any rate, of the accepted tender: it adds to the value of the information.

CATERHAM.—For additions and alterations at Thornhill, Caterham, Surrey, for Mr. Andrew Lockie. Mr. Chas. H. Wiltshire, 13 and 15, Walworth-road, S.E., architect:—

Thompson £1,150 0 0
Hoskins (accepted) 1,093 0 0

ACTON.—For alterations and additions to the Priory Board Schools, Acton, W. Mr. Edward Monson, jun., F.R.I.B.A., Acton Vale, W., architect:—

Sole and Son, Richmond ...	£4,600 0 0
Flaw and Co., West Kensington ...	4,487 0 0
Tozer, F. R., Notting Hill ...	4,282 0 0
Bagge, T., Acton Green ...	4,261 0 0
Whitehead and Co., Clapham-road ...	4,250 0 0
Tout, W., Hendon ...	4,250 0 0
Billins, J., Hounslow ...	4,214 9 0
Jarvis J. H., Surbiton ...	3,975 0 0
Lascelles and Co., Bunhill-row ...	3,973 0 0
Martin and Co., West Croydon ...	3,947 0 0
Chapman, J. G., Hounslow ...	3,944 19 10
Martin, A., Battersea ...	3,895 0 0
Lyford, G., Shepherd's Bush ...	3,857 0 0
Akers and Co., South Norwood ...	3,750 0 0
Hooper, G., Acton ...	3,740 0 0
Bray and Clayton, Acton ...	3,736 16 0
Nye, T., Ealing ...	3,697 0 0
Tollinson, J. F., Teddington ...	3,560 0 0

* Accepted subject to the approval of the Education Department.

BATTERSEA, S.W.—Alternative tenders (a) for providing ceilings of fibrous plaster, and (b) for match-boarding twelve ceilings at Shillington-street school, Battersea:—

	A.	B.
Mowlem and Co. ...	£295	£236
Nightingale, B. E., Albert Embankment ...	292	165*
Charteris, D. ...	230	206
Holloway Bros. ...	229	260
Hammond, W. ...	228	244
Lathey Bros. ...	210	235

A.—Fibrous plaster. B.—Match-boarding. * Accepted.

BATTERSEA, S.W.—For fitting up the schoolkeeper's house at the Latchmere School, Battersea Park-road, as a cookery centre, for the London School Board. The Committee proposed that the house on the site, previously in the occupation of the schoolkeeper, should be adapted for this purpose. Tenders were accordingly invited for carrying out this work, but as only four tenders were received, the lowest of which was in excess of the architect's estimate, fresh tenders were invited from seven contractors, one of whom, however, was unable to submit a tender. The amounts of the tenders in the two competitions are set out below:—

A.—First competition:—	
Hammond, W. ...	£875 0 0
Derry, J. ...	863 0 0
Holloway Bros. ...	844 0 0
Garratt and Sons ...	810 0 0
B.—Second competition:—	
Parsons and Co. ...	£835 0 0
Kent, G. ...	254 0 0
Garrett and Sons ...	250 0 0
Barker, E. ...	250 0 0
Triggs E. ...	220 0 0
Humphrey, C., High-street, Fulham ...	199 10 5

* Accepted.

BIRMINGHAM.—For the erection of two houses in Livingstone-road, Handsworth. Mr. H. Hugh Allen, Small Heath, Birmingham, architect:—

Squires (accepted) £590 0 0

BIRMINGHAM.—For the erection of two houses in Tennyson-road, Small Heath. Mr. H. Hugh Allen, Small Heath, Birmingham, architect:—

Edmunds (accepted) £730 0 0

DORKING.—For building a private residence on the Holloway Estate, for Mrs. Randall. Mr. F. J. Dibble, architect:—

Edser ...	£1,377 0 0
Canter ...	1,339 0 0
Goddard and Sons ...	1,195 0 0
Colls and Sons ...	1,275 0 0
Hamblin Bros., Dorking (accepted) ...	1,225 0 0

DUDDINGTON.—For erection of new schools and out-buildings at Duddington, near Stamford, Northamptonshire. Mr. J. B. Corby, F.S.I., Stamford, architect:—

Hipwell, S., Wisbech ...	£885 0 0
Peasgood, J., Stamford ...	840 0 0
Halliday, S. F., Stamford ...	796 0 0
Dean, W., Uppingham ...	751 0 0
Roberts, A. S., Wakerley ...	747 0 0
Bowman, E., Stamford ...	745 0 0
Perkins, W. and J., Easton ...	737 0 0
Robert, B. W., Stamford (accepted) ...	685 0 0

ZINC ROOFING.

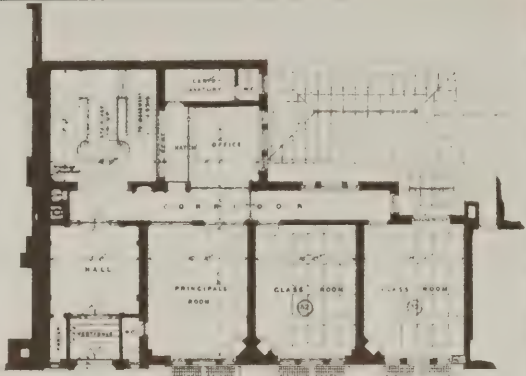

COPPER ROOFING.

SOLE INVENTORS and PATENTEES of SOLID STOPPED ENDS, &c.

THE BUILDING NEWS

AND ENGINEERING JOURNAL.

VOL. LXIII.—No. 1979.

FRIDAY, DECEMBER 9, 1892.

UNSOLVED PROBLEMS.

THERE are some things which baffle the resources of the architect, or of those who desire to erect buildings which shall satisfy all scientific requirements, and yet be amenable to certain canons of good taste which we call artistic. Quite true it is that the greatest effort of skill in architecture, as in engineering, is required in satisfying apparent irreconcilable requirements; in short, that it is the conquering of what seems to be an insuperable obstacle that constitutes the greatest merit in a work of art. Whenever the problem is easy and smooth the mind is apt to relax its effort, and to fall into commonplaces. It thinks what has been so often done before will do again, and the design, whatever it may be, becomes a repetition of one type or building. The domestic architect who has a large practice in house-building will need little more effort than an ordinary share of skill. The requirements are much the same; walls and roof admit of no new departures, and no new materials have to be introduced. The man who has a large business in designing commercial premises seldom has anything very novel to carry out; probably his chief *crux* is the necessary disguising of the iron girders and columns, if he troubles about them at all. The church architect, again, has seldom any problem to solve, if he adheres to the Mediæval model—one reason why so many churches are characterless copies. It is only, indeed, when he seeks to introduce a new feature or adopt another way of doing something—such as a narthex or baptistery or treatment of chancel, or eastern termination, that he overcomes the temptation to follow some old model and the inertness of commonplace. We have conspicuous examples of this freshness in the late Mr. Sedding's work, and in churches erected by the late Mr. Street, Mr. Pearson; in the new churches of St. Philip, Stepney, All Saints', Dulwich, and others. With these exceptional instances there has been an easy compliance with the dictates of style and fashion; it has been simply the following of a formula. But when any new departure has to be made, the architect has to set aside his formula and begin to discover a mode of construction that will give the required result, he has to exercise his artistic power on a new problem, and it is then that his real ability as an architect is seen.

We will endeavour to point out one or two directions in which new building problems present themselves. Let us take an exhibition or market building which has to provide a large covered area. The mere builder may assume that any huge shed will do; but such a solution is not architecture. Then the roof must be of iron, of stability enough to resist the vertical pressure due to weight and the stress of wind; it must be constructed to admit light. Its form and construction must be determined by the shape of the area covered. A precedent may only hamper the designer by excluding from his mind any original idea. We have plenty of instances where genius has been stifled in the initial stage, leaving a costly blunder as a warning for all time. For constructional ingenuity and skill, probably the experiments now being made at Chicago for the Columbian Exposition buildings have not been surpassed; but the immense spans of the roofs have led rather to a display of *tours de force* than good design. The Liberal Arts building, with its huge trusses of braced steel of 368ft. span from centre to

centre of pins, and of 205ft. rise, is a fine example of trussing; the main building of the Machinery Hall is another immense rectangle about 850ft. long, and nearly 500ft. wide, covered by three parallel rows of circular shaped lattice arches or ribs, each of 130ft. span and 57ft. rise, the springing line 36ft. above the floor. Each arch is pivoted at the springing and crown, which allows for the rise and fall due to temperature. These three parallel rows are crossed at the centre by a transept of three low circular domes, each of 130ft. diameter, with lanterns over each. There is here the germ of an architectural structure of metal if only better proportions had been given to the domes. We hear one exclaim, Can any architecture be got out of steel? We must boldly take the bull by the horns and make something of these skeletons of iron. If we can only give them agreeable proportions, and put them in the right position to form a good roof, one step of the problem has been taken. The second is how to improve the details of lattices and bracing. In the design of these structures, the setting out of plan—that is, how to dispose the roof—is the main thing, and no doubt to preserve certain ratios between the length and width, the distances of the roof trusses apart, and the heights of the different parts of the inclosed area contribute towards the result. But architects have thought too much of adopting ornamental trusses and accepting old plans of buildings of very different materials and objects than to trouble about thinking of a new problem, so much easier is it to vary and elaborate old forms than to design something original.

Another bugbear of the architect is the acoustical building. A most careful study of the theory of acoustics does not help him one iota. He may be told that certain buildings are almost perfect in this respect, and he adopts their proportions, only to find that some other conditions to success are wanting. The most costly, handsome, and architectural interiors are bad both for speaking and music, while some temporary or plain apartment has admirable acoustic properties. No one can explain why the most commonplace hall or lecture-room in the town is so good for speaking in, while the costly and recently-built town-hall, designed by an eminent London architect, has been denounced by all speakers and musicians. But the fact remains. All the architectural expedients of groined coves, elaborate panelling, lanterns, have added nothing to the acoustical qualities of the room, but have rather broken up the sound and created noisiness and echo. All the angles of the new town-hall are rounded, the platform end has been made curved, but still the voice is not clearly heard at the other end. The old room with its plain walls rectangular shape, and flat ceiling of ordinary height, is in every way superior for meetings and lectures. The fact astounds the architect. His study of acoustics and his theories about forms have not borne any fruit. Why? Because he has been satisfied with designing his plan and section first, before studying those properties and details which have been found to give the best results acoustically; contented if he tries in matters of detail to satisfy the requirements of certain laws. In plain fact, the acoustic conditions are not discovered and applied to a room or building from the first, but are sought to be worked back to, or introduced afterwards, by cutting off the angles of room, by making the platform end circular, or confining the sound within the orchestra by a lower ceiling. The result is remedial, not constructive. The problem is to design the room so that it may comply with the laws affecting the propagation and transmission of sound, and at the same time be architectural in shape and details. But the architect stands aghast at such a problem, instead of

boldly attacking it. How can the form and proportions of a trumpet or violin be applied to a room; how is the important law of sympathetic vibration to be fulfilled in the construction? Again, the fact is well established that a room that is good for speaking may be bad for music, and *vice versa*, so that there is another initial difficulty here, for it is known that the vibrations which produce musical sounds are periodic and regular in their intervals, while those which are unperiodic and irregular produce noise, and in the latter category is speech. Dr. Robert Hooke, in fact, a century ago, showed that musical sounds could be produced by the teeth of wheels made of equal size; but for vocal sounds they had to be of unequal size, so as to produce unequal strokes. But how are these two laws to be applied to our churches, chapels, concert-halls, and lecture-rooms? If it be a fact that sound can be reinforced by setting up a vibration in bodies which will vibrate to the same note, how can this rule be applied to a church, where both vocal and musical sounds are produced? We can easily illustrate this law by the simplest experiment with a tuning-fork applied to a sounding-board or organ-pipe, to prove the value of sympathetic vibration in a room destined for musical performances. If the architect can regard his building as an inclosed space of air, a reinforcing body, then it seems to follow that he may give it such ratios of length, breadth, and height as will insure the production of musical sounds. This, at least, is the conviction of many, and the burden of some interesting remarks lately made by Mr. H. C. Kent, M.A., before the Sydney Architectural Association.

For speaking purposes a circular or horseshoe form of plan is supposed to give the best results, the dimensions of which are limited to a distance in front of the speaker at which he can be heard, and to a distance on each side and behind him. Wren gave 50ft. in front of the speaker, 30ft. on each side, and 20ft. behind; Saunders has given 92ft. in front, 75ft. on each side, and 31ft. behind; but these dimensions are approximate, and cannot be always relied upon when so much depends on the materials, and especially on height. The latter should be limited if undue resonance, absorption, and reflection of sound are to be avoided; and it is generally considered that the space behind the speaker should be contracted in width and height, and partake rather of the trumpet form. But for buildings for orchestral performances, harmonic proportions of simple ratios are the best to reinforce the musical sounds. The ratios of two to three to five or six have produced successful results, or a height of 52ft., a width of 78ft., and a length of 130ft. For buildings adapted for music height does not seem to be destructive or prejudicial, as our lofty cathedrals and churches afford good examples of the value of a body of resonant air to give support and richness to the tone. Very little will be done, however, till architects begin to think out for themselves the solution of this and other cognate problems in architecture, so as to arrive at some definite type of structure, rather than being content to follow old examples. Careful experiments of transmission of sound in different buildings, both for speaking and music, would lead to some valuable results from which principles might be deduced.

WINDOW DESIGN.

LITTLE attention is given to the modes of setting out and spacing window openings. We find architects following a certain style with a blind adherence to some example rather than pursuing a definite principle in the design of their elevations. The rule of studying plan and elevation

simultaneously hardly appears to be followed. An elevation is sketched out after the plan has been made, and the openings are left to take their chance. Lucky if they fall into anything like order or good spacing. The amount of light and the height and width of each opening are questions that first demand the thought of the designer, as upon these points the relation of opening to wall space will be regulated. If the rooms are of some depth from front to back, the windows ought to be proportionately large or high; but if shallow, they may be made smaller. Our remarks here, however, concern the design of windows in a façade as one of the means of expression, and this, it must be confessed, is a subject that has given way largely to question of mere style. There are, it appears to us, two main causes of failure in the design of our façades: first, the crowding of small windows, and second, the want of distinctive character in their design.

A number of equal-spaced windows in a front is distracting and unsatisfactory, and is generally the mark of inferior design. The second fault has arisen mainly from the idea that an elevation is a given space which has to be filled with windows and pilasters and other decoration without any regard to solids or voids. The lesson for the designer to learn is the effect of altering the proportion of opening to solid walling, for if he once understands the result of the alteration, he can bring the resources of his art to the problem. Let us for a moment consider the subject in an experimental way. Suppose there are three windows, the two intervening wall-piers being each, let us imagine, equal to the width of opening. Let us further imagine the windows to be perfectly plain openings in a flat wall, and, say, of the proportions of double squares. Above these openings are three others of similar size and proportions. The effect upon the eye is that there is as much solid as void, the windows look what they are, simply openings, and there is no design worthy the name of architectural in such an arrangement. A wall pierced by oblong apertures at regular intervals can have no design except mere mechanical division. There is enough of the wall to be recognised as such. We may surround each window with a moulding or architrave, which will tend to disguise the hole-in-the-wall idea a little; but this framing does not alter the effect. But let us introduce a pilaster or a column in each of the two intervening solids, and the interest will be immediately centred on the piers. A little importance may be gained for the windows by placing pediments upon them, and converting their jambs into pilasters; but still the piers will retain their prominence, and the façade will be visibly enriched by the change—be made, in fact, architectural, the whole effect heightened. Any Italian Renaissance façade illustrates this kind of design. We may widen the piers, making them one and a half of the windows, but still they will not lose the essentially pier character, but if we widen them still more—say, to three-window widths—the wall character will return.

On the other hand, let us make the piers narrower. They will assume more and more of the mullion character. So that by this little trial we have learnt two things: First, by planting a column or a pilaster on a pier between windows we can change entirely the character of the design, and convert the wall into a pier, altering entirely the hole-in-the-wall look of the front, and by narrowing the pier we may give it a mullion character; secondly, by widening the intervening wall-space we give the wall importance. Now let us consider the matter from the window point of view, instead of the pier. By narrowing or emphasising the pier the window assumes less importance architecturally and its hole-like character totally

disappears; on the contrary, when the piers or wall spaces are widened the window becomes a feature, and attention is centred upon it more or less, according as it is pronounced by ordinances or decoration.

This general and broad division of the subject, therefore, naturally suggests, first, attention on the *window* opening, and, second, on the *pier* or *mullion*. When the window area is, therefore, reduced in comparison with the wall, the eye at once is arrested by it, its form and decoration, but when it occupies a large area proportionately, the solids come into notice. This consideration may help architects to decide when they ought to pay attention to the external decoration of their windows, and how they might give some character and expression to their designs by taking into account the disposing of their piers and mullions. At present we see very muddling arrangements; some architects appear to think that there is no art in window distribution, that it makes little difference whether they are near one another or far apart; they imagine that close-set windows ought to have as much decoration as those with considerable wall space around them. Two things are pretty evident—namely, that in commercial buildings in which large windows or open fenestration is necessary the design of the elevation will be mainly in the distribution and arrangement of the piers or mullions; but when the apertures are small, these apertures require the chief consideration, and a large amount of ornamentation may be lavished on them. The window may be looked upon as a point of interest—like a framed picture on a wall. In the Italian Renaissance, it may have the usual ordinances of engaged columns, entablature and pediment, with plinths, and balustrade below; or the Palladian decoration, consisting of a pediment supported on consoles outside the architraves, which we may see in the Banqueting House at Whitehall, or the rusticated forms we see at Greenwich Hospital. All these are so many different ways of framing the window and making it a distinctive feature on the decoration of the façade; the wall in this case is neutral, and appears simply as a background to the windows.

We see buildings where the apertures are so distributed that no distinctive feature is made of them, and the wall space is frittered with pilasters and other ornament. These designs fail, because neither the pier nor the window has any distinctive character in the design. Many of the hotels in Northumberland-avenue have been spoilt by non-observance of the simple rule, and the result is a confused arrangement, the eye is distracted by a multiplicity of small openings and details instead of being led to the windows or the piers.

The effect of spacing and distribution of window openings is one of the most powerful in the limited means of the phonetic in architecture. A building pierced by a few small apertures, like a fortress or a prison, has all the heaviness and gloominess characteristic of those structures. On the contrary, the open fenestral façade awakens sentiments of precisely the opposite character. Even the ignorant in architecture are affected variously by the proportion of wall to window. There is something austere and repellent in the crenellated and machicolated keep, gay and attractive about Henry VII.'s Chapel, or the King's College Chapel, Cambridge. The relation of solid to void appeals to our sympathies, and is one of those elements of the poetic in architecture which must ever be recognised.

In London, Manchester, Leeds, Glasgow, we have opportunities of studying the two kinds of fenestral composition referred to—the former the mullion treatment, and the latter the pierced wall. Contrast Barry's noted Reform Club-house in Pall Mall with that of the Army and Navy

and Carlton Clubs; or, to refer to more recent examples, let us take Mr. Norman Shaw's New Scotland Yard front and St. Stephen's Club-house: one has the solid wall pierced by apertures, the other is made up of piers and mullions. In the commercial parts of the City, and in Manchester and other towns, the window has gradually become to mean an arrangement of voids divided by mullions, the wall disappearing in the demand for glass. Sometimes this style of façade assumes the appearance of a framework made up of uprights and transoms, the apertures being all windows. We have many other examples of this sort to be seen in Oxford-street and in the City, in which the windows constitute large open panels divided by strips of masonry.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

AT the meeting of the Institute, held on Monday evening, the President, Mr. J. MacVicar Anderson, introduced to the members, in a few cordial words of welcome, Mr. William Emerson, who was at the business meeting held a fortnight previously unanimously elected honorary secretary, in succession to Mr. Aston Webb, resigned. Mr. Emerson briefly returned thanks.

The President stated that the Council had awarded the Ashpitel prize of books having the value of ten guineas to Alfred Charles Houston (pupil of James Edmeston), he having, in the opinion of the examiners, most highly distinguished himself in the examinations in architecture during the past year. High commendation had been given by the examiners to Harold Brakespear, of Manchester, and the Council had, therefore, awarded him a special second prize of books value five guineas.

SOME PROBLEMS OF TOWN AND CITY DEVELOPMENT.

Mr. WILLIAM C. STREET read a paper on this subject illustrated by several diagrams to large scale, including Sir Christopher Wren's original plan for the rebuilding of London and a sketch, prepared by himself, of a radial or spider's web plan for the ideal development of a town on the bank of a river. This gridiron sketch might possess some merits of economy and convenience, but was forbidding in effect, and was received with general disfavour. Mr. Street argued that in the extension of any large city, architects and public authorities should show more consideration for the surroundings and requirements of the population, and should work in accordance with an approved plan for future development. A great enemy to any such beneficial development had been the land-grabber who, having purchased land in the outskirts, planned as many streets as possible for the sake of the ground-rents. Good main thoroughfares, with ornamental open spaces at convenient distances between them—the minor streets being sufficiently wide—were to be desired. In certain cities regulations existed to prevent the building of dwellings outside certain limits until the intervening spaces were filled up in accordance with an agreed-upon scheme. Such stringent regulations might at first frighten those who looked upon so-called natural developments alone as being beautiful; but that was an open question. A square or rectangular development, as of American cities, the author thought, was unnatural, the tendency in all cities being for the traffic to pass and repass upon lines radiating from the centre where the principal business was conducted. The impression given by such radial development was far from unpleasant. Mr. Street considered the separation of the classes neither healthy nor natural. In laying out a district it was better for the health of the dwellers in the main avenues that in the minor streets adjacent the buildings should be less in height than those in such avenues, the air at the back of the higher buildings being open to the circulation of currents at a lower level, and not so stagnant and unhealthy as when the space was inclosed on all sides by lofty buildings. In laying out open spaces, the dank, circumscribed, and prison-like look general to London squares should be avoided; and the provision of large parks, stiff, flat, and uninteresting, was not at all what he intended. Having quoted 45 Vic. cap. 14, sect. 14, with reference to air-space round buildings, the lecturer said the provision of practically a strip

of open space 10ft. wide at the rear of a building, while it might be sufficient for some buildings, would be manifestly inadequate if the building was of very great height, and, any regulation in regard to open space should have reference to the height of the buildings. The revised regulations of the proposed General Building Act might, he thought, be that no building whatever should hereafter be erected of a greater height than the width of the street, and that every building in the rear thereof should have a strip of land belonging to it of a minimum width equal to one-fourth the height of the building; the height of the one-story building to be allowed in the open space should also be limited, 12ft. to the eaves being the extreme limit. By the London County Council (General Powers) Act, 1890, no building was to be of greater height than 90ft., and in the draft suggestions for a new Building Act, that maximum height was reduced to 75ft., and might, he thought, be further reduced with advantage. Under those suggestions, when streets 50ft. wide ran in parallel lines, and the buildings were 40ft. deep, there would be two 40ft. front buildings, and two 12ft. 6in. open spaces; the distance between cross-streets being 105ft., or 150ft. from centre to centre. A blot on that arrangement would be that houses in the main thoroughfare would hinder the access of air to the space at the back of the houses on the cross streets, and, therefore, there should be a minimum width of 25ft. between the backs of houses in the main road and the sides of those in cross-streets. The Model By-laws recommended a minimum width of 25ft. for all houses of a height of 35ft., or more, and if that were generally adopted air-space around buildings would be liberally provided for. As to street improvements, the width of 40ft. seemed to be fixed for subordinate developments, and in some thoroughfares recently constructed the width of 70ft. had been adopted. Subways should be constructed under all main streets, and the several gas, water, electric light, telegraph and telephone companies paying rent for the space occupied by their mains would practically repay the cost of construction. Mr. Street turned to the question of dwellings for the labouring classes, and deprecated the erection of large blocks of these buildings. London, far from being overcrowded, did not accommodate one-eighth of the number of people that was possible on a similar area, as 400 persons could be housed in block buildings on one acre, allowing an average of 2,000 cubic feet to each person; at present the proportion was 54.4 per acre, and if the erection of lofty blocks was at all likely to bring about such theoretical limits, that of itself ought to be a sufficient reason for discontinuing their erection. Small tenements might be expensive as compared with blocks, but there might be advantages to counter-balance that of cheapness.

A discussion followed, in which Messrs. WILLIAM WOODWARD, LEWIS ANGELL, of West Ham, ARTHUR BAKER, HENRY DAWSON, H. MACLACHLAN, P. GORDON SMITH, architect to H.M. Office of Works, BOND, late surveyor to the Charity Commissioners, and THOMAS BLASHILL, superintending architect to the London County Council took part.

ARCHITECTURAL ASSOCIATION.

THE fourth meeting for the present session was held on Friday evening, the President, Mr. H. O. Cresswell, in the chair. The following five new members were elected:—W. E. Sedgwick, W. R. Davidson, H. C. Trimnell, C. Perks, and A. J. R. Ley.

DAYLIGHT IN THE DWELLING.

Mr. JOHN BRETT, A.R.A., F.R.A.S., read the following paper on this subject:—In inviting a painter to read a paper to you this evening, your committee do not necessarily imply that a painter can be an authority on architecture; but that he may, perhaps, know one or two things about the lighting of a house that are not usually learned in architects' offices, but which yet may have some practical importance. No other profession in the world has such control over the destinies of men in general, but specially of painters, so I feel sure you will good-naturedly consider their wants before you put in your windows. We shall all readily admit that the first requisite for a dwelling-house in this climate is that it should keep out the weather, and it can

easily be shown that the next essential quality is that it should let in the daylight (when there is any). I propose to explain in the first place what good lighting means, and how the windows should be placed so as to enable you to see things well inside the house. My next endeavour will be to show how the daylight, having been admitted, can be economised and utilised by reflection, and that the artistic treatment of the interior largely depends upon reflected light and on the quality of the reflecting surfaces. You can have a very comfortable life in a tent, and a considerable portion of mankind for generations have found tents quite good enough for common purposes—to eat, to sleep, and to die in. But civilised man has a want which a tent cannot supply—viz., a place for the exhibition of his treasures, especially the treasure of beauty, for which stability, permanence, and good daylight are wanted. He also requires a base of operations for his enterprises, a museum for his archives and trophies, and, above all, for the convenient arrangement of his intellectual resources—for his books and his pictures. He may also require means for the entertainment of his neighbours and his children, and for seeing them to the best advantage. If you can admit that a painter knows anything, you may be sure he knows how to light a picture so that its merits may be well seen, and I think the lighting of pictures is an excellent criterion of the lighting of the house—indeed, a very crucial test of it; but it is evident from our daily experience that many architects have never heard of such a principle, and will exclaim with certain disciples of old, "This is a hard saying. Who can hear it?" Now, it is not practicable to build for a single individual; you must build also for his guests and for the public. Your client may be the most ignorant vestryman in the three kingdoms, but he will not owe you any thanks if you work down to his own personal level. Even if he devotes his whole life, say, to the choosing of bacon or cheese, he will still like to leave behind him when he dies such a house as shall have the approval of the more cultivated men of his day. Therefore you must provide for the housing of works of art, although they are not mentioned in the specification. When you have done your best the house is sure to have defects. Some of these will probably carry with them compensating advantages, and some can easily be lived down by a philosophical tenant; but defective lighting you will find very difficult to deal with, and in most cases incurable. Daylight is more or less necessary for our physical health, for cleanliness, for the preservation of our possessions from damp, from mildew, and other enemies, but it is indispensable for the seeing of beauty. A large quantity of daylight is not the chief consideration. A glass house or a lantern is eminently unfit for a human dwelling, since snugness is a most desirable quality, and for your banquets artificial light is better than natural daylight, as I will explain later on. The most common form of beauty harboured in houses consists of pictures. I use the word pictures in a broad sense, comprising all such beautiful things as can be shown on the walls. I do not refer to the great art of sculpture, because that is considered by many of us as an essential part of architecture. The daylight under which pictures can be well seen may be either direct or reflected. If direct, it should *not* fall normal to the surface. It may come from the right or the left, or from the top; but it must not come from behind the spectator, for two simple reasons. The first reason is that his own shadow will fall on the field of view, and the second that the surface of the picture will shine; so that the wall opposite the window is not a picture-wall. The aspect of the window is not of much consequence, for although direct sunshine kills delicate colour, and is not adapted to show anything well, it can generally be diffused sufficiently for most purposes by a blind of fine texture, and the architect is not much concerned, because the exigencies of the site and the plan will already have determined the aspect for him. The subject of skylights may be put aside for the moment, and windows taken to mean perpendicular openings in the wall. The placing of them should be decided simply on utilitarian grounds—that is to say, how the most wall space can be well lighted. External appearance need have no weight in the argument, for a man who cannot make any possible windows compose well in the elevation is not an artist at all, and, therefore, not an architect. I may even go so far as

to say that the more irregularly, unsymmetrically, and arbitrarily they are placed, the more scope there will be for developing a picturesque building. From an outside point of view—that is as far as the public are concerned—picturesqueness is the happiest attribute to be hoped for in a domestic building, since it will seldom be large enough to have any claim to sublimity or impressiveness. But there is this to be said on the other hand, that there is no worse form of affectation than the effort after picturesqueness for its own sake. In streets or terraces there is not much room for choice in the placing of the windows, so we generally find such houses comparatively well lighted. It is where the phantasy comes in, as in the country house or the villa, where your architect is rampant, that you may expect to see some artistic flourishes, constructive mistakes, and incurable lighting. If you design your house strictly from the inside, and on merely utilitarian principles, a good external effect is inevitable, or can only be missed through a singular degree of ignorance or meanness. Of course, if you are ignorant of construction, or if you want to produce a more gorgeous appearance than you can honestly afford, there is no redemption for you; you are bound to fail and to wish that you had never been born, for a mean building is usually destined to encumber the earth, and to disgrace your name for at least ninety-nine years. Let us at once assume that your client or his heirs will have some beautiful things to grace the inside of their dwelling, and we should not overlook the circumstance that his daughters may be comprised in this category, so we must be careful to light carefully this living sculpture, no less than the flat surfaces of the wall pictures. A happy expression on the human face is largely dependent on reflected light, which concerns surface treatment rather than construction; but the fundamental consideration and root of the whole art of lighting depends on having only one single aperture in the wall, so that the direct rays may all enter parallel, and not in conflicting directions. In artists' studios you will always find this rule carried out, and I will now attempt to explain the reason for it. Let us suppose you have to draw a portrait. A single high-light on the head involves a shade in exact proportion to it which you, as a draughtsman, can supply without any chance of error. The cast shadow likewise will have a known, well-defined and inevitable relation to the shade. The simplicity of light and dark enables you easily to grasp the form, and to appreciate its undulations without uncertainty or confusion; whereas, if you have two sources of light allowing rays to enter in two different directions, not only will you get on your model two high lights in inconvenient rivalry, but all your shades will be complicated and put out of their normal relation to their lights. The unity and simplicity of one shadow will be marred by the intrusion of another, and the result will be that your apprehension of the real undulations of the surface and the beauty dependent on them will be hindered, and considerable spaces of the surface will have no meaning for you—the beauty revealed by one ray of light being neutralised or blotted out by others proceeding in a different direction, so that the seeing is very considerably impaired, and the form shown at disadvantage. This is one important argument in favour of establishing only one inlet of light in each room. But there is another argument even more important, because it affects not merely the form of an object, but also its colour and texture; in fact, it fundamentally affects your seeing power. The subjective effect of cross lights is to diminish the pupil of your eye, thus curtailing absolutely your physical power of vision. In order to use all the seeing power that nature has provided you with, it is necessary that the light should reach your eye *after* having illuminated the object you want to look at; and, further, that the pupil of your eye should be encouraged to open to its full size by being shaded from the glare of direct rays. As all architectural structures have upright walls, such as are very convenient to look at, it is important that they should be well flooded with daylight, so as to show such pictures as you have; and next, it is advisable to economise those walls as fields of beauty, and not carelessly cut them up by chasms for doors or fireplaces. Seeing that your house is not to be a mere shelter, or casual ward, but an intellectual preserve, it is worth while to relegate such interruptions of wall-space as far as practicable to the corners. I know that there is nothing more

painful to the soul of the modern architect than a blank wall, and that sleep for him is impossible until he has broken through and destroyed that invaluable area of repose. So mad does it make him that he has been known to build in unnecessary pilasters in order to divide it up. I will venture to remind him that the impressiveness of a building from the outside largely depends on great unbroken areas of wall, and that these may be well studied in Mediaeval fortresses, which are admitted to be the most picturesque structures existing in Europe: take, for instance, the castle of Ivrea in Piedmont. It may be taken as a general principle that any architectural design that is so complete in itself as to forbid the intrusion of the subsidiary arts is not adapted for a dwelling-house. I know a man whose house was finished by Owen Jones. He is very fond of pictures, but has to keep them piled up in stacks for fear of spoiling his walls. We have now arrived at one well-defined and very important rule, which is that the daylight should be admitted to a room on one side only. That part of a window which is most valuable is the top half, as it admits most light per square foot. The lower part only admits light reflected from the earth, and more or less coloured; therefore, roll-blinds from the top should never be allowed. Any other form of curtain is less mischievous, but a roll-blind should be fixed at the bottom. In a well-lighted house the windows are carried right up to the cornice. Window heads, whether traceried or lancet, may be admirable, but should be reserved for other buildings where people do not dwell. If you ask yourselves the question which rooms are pleasantest of all those you have known, only one answer can be given, and it will be this: Those rooms are pleasantest in which work is done. Few would reply, "Those from which you have the best view." The man who would say so must be one whose home is sad, solitary, and unlovely; whose memories are the only beautiful visions on which his thoughts can linger. How often do you resort to your window with relish and turn away from it with reluctance? In your town experience I may confidently reply, "Never." If you decide the question by the suffrage of all the fairly cultivated men and women you know, I think the vote would be given in favour of the painter's studio, which has either a skylight or a window too high to look out of. Few, even amongst women, would vote for the drawing-room. It does not usually fall to the lot of gentle-folks to spend much time in workshops, but if you have a wide experience you will cherish the remembrance of the days you have spent with the goldsmith, the blacksmith, or the carpenter, and none of those shops were lighted by architects, none of them had any outlook. If you would rather look out of your nest than into it, then must your life be sad indeed, and you had better get away into the wilderness, or to the top of the Hindu Kush. There is in the city of Timbuctoo a great town house which illustrates nearly all the blunders that can arise from ignorance of lighting. The Sheikh is a man of the utmost good nature and nobleness of soul, and takes pleasure in his splendid possessions just in proportion to the number of intelligent men who will share their enjoyment with him, so I surmise that some of you have been his guests. He has a collection of pictures of first-rate importance, but his ingenious architect has so contrived the interior that hardly any of them can be well seen. The value of some of the pictures is so great that a very few of them would cover the cost of the whole building, yet many of them are condemned to blush in dark corners in order that the architect should indulge his childish taste for symmetry. The principal suite of rooms face the south, and are all lighted in the orthodox way, viz., on their long sides. The opposite long walls do not afford any good lighting, because your own shadow and the shine on the pictures conspire to render them invisible; and the gigantic fireplaces occupy about a third of the area even of these walls. The only well-lighted spaces that the plan allowed were the short walls that stand north and south. These he had wantonly and ruthlessly wasted by opening a vast doorway in the middle of each of them big enough for the gate of a city, and so the design was finished. Many architects would be surprised if they knew how fine an effect is produced by entering a room at the corner instead of at the side. It must be very unusual, since I do not

know more than two or three instances of it. Its charm depends on the varied angles under which the walls present themselves to the eye when you enter, as all of them are seen under oblique instead of parallel perspective, and the suggestion is conveyed that you should go on and prosecute your researches in the ramifications of the structure. You are not confronted by a flat opposing partition right across the line of advance. All deviations from mere symmetry are dear to the soul of the artist because they give occasion for composition—that is to say, the creative faculty—and if there were no other reason for placing a window out of the centre of the wall, this would be sufficient; but as a matter of experience many reasons for doing so are not far to seek. There are instances in which one whole wall is filled in with glass, and with excellent effect. There is one in a house at Putney very near my own built by Mr. Waterhouse. It is the window of a fine staircase, the other whole walls of which are well lighted and well adapted for pictures; but, alas! the use of stained glass in the window has put this out of the question; and instead of an intellectual feast of fine art, you are indulged with some admirable colour and design in the glass itself, but the walls are wasted. Let us now turn our attention to the second division of our subject, and determine how to deal with the daylight when we have let it in. This important question is too often shirked by the architect, and shuffled on to a scapegoat called the decorator. This pernicious person has the power of doing immense mischief at small expense, so he does it with no niggard hand. For a concrete example, let us refer back to the great house in Timbuctoo. The picture-show begins at the dining-room, the walls of which are covered with a rich stamped leather of dark maroon and gold, affording a fine background both for pictures and guests. The decorative mind was just able to grasp this principle, and, knowing there was "nothing like leather," he carried it right up from floor to ceiling, absorbing that part of the wall which is too high above the spectator to be serviceable as background, and destroying its power of reflecting light, which is the only function it could have fulfilled, and would have fulfilled with admirable effect if its surface had been tinted with tempera or an ordinary wall-paper of a cream colour. The ceiling, as usual, is cut up with mouldings and colouring of senseless pattern; but even if it were well designed, he would surely be an odd sort of visitor who would turn away from Vandeyck or Sir Joshua Reynolds to gaze at the ceiling. A few six-penny buckets of whitewash expended on that ceiling would have redeemed the room, and proved that it belonged to an intelligent human being. There are two different conditions under which light can be reflected. They are known in optics as whole light and scattered light. Whole light advances in one direction only. An ordinary plane mirror reflects whole light. Scattered light proceeds in all directions at once, and cannot be focussed by the eye so as to show images. Such is the light reflected from any granulated or dead surface, such as tempera, snow, or sand. If you require a polished surface to reflect light into a dark corner, it will fail to do so unless it is placed at exactly the proper angle, whereas a scattering surface will be efficient at any angle. All surfaces that are not strictly required to do duty as backgrounds should have a scattering surface, so as to diffuse the illumination, and the lighter their colour the more efficient they will be for this purpose. In Italy, unfortunately, there is more or less good art displayed on the ceilings of the great houses. All men who have seen it will agree that it could not have been more foolishly misplaced, or more effectually wasted. An excellent reflector of scattered light is a white linen cloth. Your architect will gladly provide you with good shelter, where a horde of menials can eat and sleep comfortably at your expense. Viollet-le-Duc is careful to go further, and provide that you shall look out on the prettiest view, but he calmly assumes that you are sure not to have anything inside your house so well worth looking at as the houses or shrubs opposite, and the historical conclusion of the whole matter is that in the reign of Queen Victoria, in nine great houses out of ten, any kind of art is out of place, for the simple reason that the architects have misused the daylight and wasted the wall-space. One word more has to be spoken as to the use of stained glass, and it is this: If you wish to

indulge in stained glass, you must make it your one and only form of colour-decoration. You can have superb colour in your window, but you take away its usefulness as a source of light, and make it an object to be looked at, and when you have looked at it your eye is unfitted to see any other colour. Even the splendid tints of Eastern embroidery or carpets cannot stand the competition; white light is absolutely necessary for the display of their beauty. Mr. Burne-Jones lately designed a beautiful picture, and Mr. Morris worked it in tapestry for the glory of the chapel of Exeter College. Some ingenious person has placed it on the same wall with a gorgeous stained-glass window, and opposite to another, so that none of its fine colour can be seen. The colour of your reflective surface is only one degree less important than the colour of your window-glass itself. A few years ago nearly every reception-room in London was papered with a dull sage green—a sad emphasis to lay on the depressing climate we have to live in; but a good man and a friend of mine was responsible for it. I am afraid you will think I display an unreasoning animus against the architect, and that I have spoken rashly and at random as to his ignorance of the use of daylight. But that is not so. There is an institution in which I lately offered to endow a prize for the best design for a house in which pictures could be well seen without a special gallery constructed for the purpose. The Council were pleased with the idea, but scoring my modest £25 a year, made it into a handsome £200. Two or three distinguished architects were appointed to judge the competition, and they actually awarded the prize to a design which afforded not one single well-lighted wall in the whole structure; and yet none of them were aware that they had done anything ridiculous! There is a good deal to be said as to skylights in lighting the dwelling-house, but you have probably heard more than enough on the sacredness of the wall and the importance of one window. Allow me to suggest, in conclusion, that these matters are worthy of your most serious study.

Mr. PAUL WATERHOUSE, in proposing a vote of thanks to Mr. Brett, remarked that his paper had raised many points on which differences of opinion existed, and it would be paying the deviser of such an architectural bombshell a poor compliment to acknowledge it with a mere "Thank you." Mr. Brett's theory that any arrangement of windows might be made into a satisfactory elevation for a house was liable to be misunderstood. In one way the lecturer had done them good service, in warning them against placing works of art exactly opposite a window; an instance of the killing effect of this disposition on pictures could be seen in the gallery at Hampton Court Palace containing the Mantegna pictures, for it was impossible to see them properly owing to the glare of light. Mr. Brett laid down the rule that there ought to be only one source of lighting for a room, and that the wall-covering ought to be selected with a view to the display of works of art; but, personally, he was inclined to doubt whether he was quite right. A large room with only an end window was insufficiently lighted for the comfort of most of those who occupied it. The lecturer had also shown too little regard for the views to be obtained from windows—there were plenty of windows even in London from which it was very pleasant to gaze. Most architects, too, would be sorry to see the decorated ceilings, say, of the Adam's period, obliterated with whitewash. As to the lecturer's strictures on symmetry in the house, while architects were doubtless too anxious to preserve symmetry at the cost of comfort, it was more desirable that regularity should be studied in a town house than in one in the country.

Mr. E. WOODTHORPE seconded the vote of thanks, but said he could not agree with much that was advanced. Direct light on a picture or the human countenance might give the most perfect definition, but the effect of diffused light was more pleasant and natural, and the fact that people looked their best when seated at dinner, with a white tablecloth before them, or behind footlights, was proof of this.

Mr. SIDNEY VACHER thought Mr. Brett had looked at his subject too exclusively from the standpoint of the painter of easel pictures. The first requirement in a dwelling-room was that it should be cheerful to live in, and this was not obtained if the apartment were a mere parallelogram, lighted from one end in order to illuminate

some easel pictures on perfectly plain wall-surfaces. He agreed with Mr. Brett that stained glass should not be introduced into a living room, except, perhaps, where an objectionable outlook had to be shut out.

Mr. MATTHEW WEBB, as a painter, agreed with much that Mr. Brett had advanced, and certainly felt that pictures in dwellings should to some extent be isolated, and not jostled together, as at an exhibition. The ideal treatment would be to decorate the walls themselves rather than to hang easel works. He believed that the museum collection of pictures had gone too far, and the extension of the system would be, he thought, disastrous to art.

The PRESIDENT, in putting the vote of thanks, said they had invited Mr. Brett as a painter to give them his views on house planning, and he thought their guest had let architects off very lightly. Mr. Brett must remember that in planning a house an architect had not a free hand, but had to meet his clients' wishes and requirements. The client really liked to see what view there was from the window while sitting down, and this meant that windows should begin near the floor level. If architects also carried out Mr. Brett's suggestions, and carried their windows to the highest practical level, so as to get top-lighting, the windows would be quite unmanageable in proportions, and difficult to harmonise with any elevation. The suggestion that roller-blinds might be fixed at the bottom, instead of the top, was a practicable one, and could sometimes be adopted with advantage.

Mr. BRETT, in acknowledging the vote of thanks, said some of the objections that had been raised to his paper would not have been raised if, instead of hearing it, members had read it in the professional papers, and had taken time to consider the points. If Mr. Woodthorpe had studied portrait painting, he would know that cross-lighting was not desirable on a face; which looked at its best under direct lighting. Mr. Vacher had objected to easel pictures, and so did he; but as people changed their houses, and yet wished to keep their paintings, it was necessary that works of art should take this form.

STABILITY OF WALLS ON SOILS.—IX.

Demonstration of Static Action of Loading on Foundation Base.

WHEN a comparatively rigid plane, as the lower surface, a, b, c, d , of the horizontal flagstone A (Fig. 23), is pressed vertically against a compressible substance underlying it of uniform density, such as a foundation soil, the distribution of the component parallel forces, making up the sum of the entire pressure, is assumed to act in one or more parallel planes, normal to the surface so pressed, and longitudinally or transversely to its rectangular sides. The orthographic projection of typical parallel planes of uniform pressure is shown normal to each other by $eeff$ and $e'e'f'f'$, standing upon the centre intersecting lines, ee and $e'e'$, of block A. The vertical arrow cr in the central intersection of these normal planes represents the position of the axis or centre of pressure R, through which the entire vertical force is assumed to act. The normal ordinate at any point in the central axis of the plane A represents the intensity of pressure at any such point along ee or $e'e'$. Then, since the ordinates at e and e' at each end of ee , the longitudinal centre axis of the horizontal plane A, are equal, and all intermediate ordinates being likewise equal, the area of the rectangle $eeff$ represents the entire pressure acting in the vertical plane $eeff$. All these ordinates being equal and equidistant, the pressure is uniformly distributed throughout these normal planes. The vertical pressures along the transverse central normal plane $e'e'f'f'$ are likewise uniformly distributed, and so likewise are all the vertical pressures within the normal planes contained in the cube $gaabb'c'g'd'$. When an inclined force as P, Fig. 24, presses in a normal longitudinal plane upon a horizontal plane, B, it may be resolved into its normal components in the same plane, i.e., one part of the force acts in a direction perpendicular to the plane B as arrow V pressing it downwards, and the other parallel as h , tending to slide it in the direction of the arrow along the surface of contact in the line yy' . The relative proportion of these component forces are represented, according to the principle of the parallelogram force, by the alternate sides of the parallelo-

gram $h V C$, by the same scale of measurement to which the oblique force P is drawn. By the principle of the equality of pressures along a longitudinal vertical plane just demonstrated the pressures at all points along xx' are equal to that which is assumed to act in the centre vertical plane standing on the transverse axis yy' of the block B. The resultant r of the uniform reaction is in the geometrical centre of the plane B, therefore the point c of application of the pressure P has a deviation from the centre r of the distance d , from r to c . When the point of application c , in which the central force p , Fig. 25, intersects the horizontal surface denoted in section by A, B, such as that perpendicular to the plane of the paper, is not in the geometrical centre of the base C, the pressure is unequally distributed over the horizontal surface. By the

method of moments, the reactionary forces are inversely as their leverages on either side of the centre of pressure C'. The two opposite equal and parallel forces applied at c' and r respectively, the second r tending to balance it equally at the centre c , and the first p tending to overbalance it by depressing the end A, create a static couple having an overturning tendency.

Essential Conditions of Stability of Tall Masonry Structures against Lateral Force.—1. The pressure at the leeward edge of a bedjoint should not exceed the safe crushing resistance of the weakest of the materials composing it—i.e., usually the mortar (see Resistance of Materials to Crushing). 2. There should be no tension or uplifting in the windward edge of the bedjoint. Note.—In order to secure this:

For Important Structures.—The centre of pressure must be confined within the middle-third of the base, or width of joint.

For Unimportant Structures.—The middle half is sometimes taken, as in semicircular arches symmetrically loaded, garden inclosure or boundary walls, &c. 3. The resistance to lateral sliding or shearing in a joint must be greater than the sliding or shearing force, by a safe margin.

Resistance of Materials to Crushing.—In order to obtain stability, the materials composing the masonry structure should safely resist the maximum splitting, cracking, or crushing force to which the moment of wind pressure may subject it, in addition to the gravity loads of the superstructure. The following safe crushing strengths will be convenient:—Portland cement mortar, 1 to 2 of sand, 10 days old, 80lb. per square inch; 20 days, 100lb. per square inch; 30 days, 116lb. per square inch. Portland cement mortar, 3 sand, 10 days old, 40lb. per square inch; 20 days, 49lb. per square inch; 30 days,

59lb. per square inch. Portland cement mortar, 4 sand, 10 days old, 22lb. per square inch; 20 days, 27lb. per square inch; 30 days, 33lb. per square inch (these are $\frac{1}{10}$ th of ultimate strengths of good grades). Portland cement concrete, 1 to 5, $1\frac{1}{2}$ cwt. to 2cwt. per square inch; Portland cement concrete, 1 to 10, $\frac{1}{2}$ cwt. to 1cwt. per square inch; lime concrete, or mortar, $\frac{1}{2}$ cwt. to $\frac{1}{2}$ cwt. ($3\frac{3}{4}$ tons per foot) per square inch; bricks, ordinary stocks, $\frac{3}{4}$ cwt. per square inch; brickwork, laid in cement mortar, $\frac{1}{2}$ cwt. per square inch; brickwork laid in lime mortar, $\frac{1}{2}$ cwt. to $\frac{1}{2}$ cwt. per square inch; masonry, rubble, lime mortar, $\frac{1}{2}$ cwt. per square inch. Building stones: Limestone, granular and crystalline, 8cwt. per square inch, soft 3 to 4; sandstone, common, 4cwt. per square inch; granite, Aberdeen, Cornish, Guernsey, 10cwt. per square inch. For recent tests of the crushing strength and other properties of building stones see Prof. Beare's paper in the BUILDING NEWS, Vol. LXII., pp. 726, 727.

Notes on Portland Cement, Tests, &c.—J. Grant's experiments led him to the conclusion that the tensile strength of Portland cement is about one-twentieth of its crushing strength; but J. Bauschinger states he has found no such fixed relation between these strengths. Cement having large tensile strength soon after setting, has a large percentage of lime in its composition, which causes injurious expansion in work. Fineness of grinding increases the tensile strength by one-half between the ground state and that passing the finest sieve, without the residue. Scantiness of water in mixing reduces the crushing strength. Thus, cement 1 to sand 3, and 20 per cent. water, gave, at 28 days old, 1,679lb. per square inch; but 10 per cent. water gave 1,425lb., or between one-sixth and one-seventh less, whereas for tensile strength there is an opposite effect. Thus 25 per cent. water (7 days old) gave 195lb., and 16 67 per cent. gave 432lb., or about $2\frac{1}{4}$ times of increase. The increase was gradual for intermediate percentages of water (Proc. Inst. C.E., pp. 54, 106, 107, Vol. CVII.)

Coefficients of Friction in Masonry Joints.—Brickwork laid in slightly damp mortar, .74; hard brickwork laid in slightly damp mortar, .70; common brickwork in wet mortar, .47 to .50; well dressed granite in wet mortar, .50; hard limestone in moist mortar, .65.

Slender Pillars of Brickwork.—Where piers are introduced in the structure a sufficient reduction of the intensity of the permanent load should be made, according to the ratio of the height to the least side, and the sufficiency of bond blocks used at proportionate intervals, the character of the workmanship, &c. Full section bond blocks should be placed at 3 to 5 diameters apart. The higher the pillar, the less the number of diameters the bond stones should be apart. Their relative number also depends on the intensity of the unit load, the importance of the duty performed, permanent character of the structure, nature of its occupation, exposure to accidental forces, &c. Piers supporting contiguous arches springing from them have their effective horizontal section for supporting the superstructure reduced to that only lying between the ends of the extradoses or top edge of the skewbacks of the contiguous arches.

Wind Force: its Nature.—The pressure exerted on structures by wind force, tending to destroy their stability, acts as a live load with momentary variations in force and direction, being influenced greatly within a certain range of altitude by topographical features and local structural surroundings, which often occasion more or less obliquity of action in producing either an ascending or descending current and eddies. The most danger to small, tall structures is to be apprehended from sudden gusts of great intensity, which produce double the effect of a static force. The Board of Trade's committee rules, reported May 20th, 1881, require in the estimates of stability of railway bridges and viaducts an allowance of 56lb. per square foot of vertical plane or lattice surface directly exposed, besides an addition of 28lb. or 42lb. for the portion of the leeward lattice girder below the rail level and above the tops of carriages when the open spaces do not exceed two-thirds or three-fourths respectively of the whole vertical area within its outline, and 56lb. when the open spaces exceed three-quarters of the entire outline. The factor of safety to be 2 when the exposure is counteracted by gravity alone. In

all other cases the factor is to be 4. Pressure on arches and piers to be computed in conformity with the above. Mr. Thomas Hawksley, C.E., F.R.S., &c., in a communication to the British Association, 1st Sept., 1881 [Reports, p. 480], considered that even 40lb. per square foot has never been experienced in this country within the range of the altitudes of existing structures.

Measure of Velocity and Pressure.—The highest wind velocity recorded of the gale of Nov. 11, 1891, was 62 miles per hour, at Falmouth. At Ben Nevis, the loftiest summit in Great Britain, whose elevation is 4,406ft. above sea-level, with a cliff of 1,500ft. high on the N.E. side, 120 miles an hour was recorded in the same gale. Mr. Dines (Report in *Quarterly Journal* of Royal Meteorological Society for July, 1892, p. 180) states that during the same gale he found the pen of the pressure-plate jump from zero to 60 miles an hour in less than half a second. Gusts of 30 to 40 miles at momentary intervals occur in every gale. The pressure-gauges erected at the Forth Bridge recorded in the storm of Feb. 9, 1889, 27lb. per square foot on 193sq.ft., and 41lb. per square foot on 97sq.ft., tending to show the intensity of pressures to be inversely as the areas.

These velocities were computed with a co-efficient of 3 on the false assumption that the cup centres of the anemometer move with one-third of the velocity of the propelling wind. They are hourly runs, presumably, which consequently minimises in the record the effect of the violent gusts by absorbing them in the hour's run in which they occur.

It is only when the anemometer has a self-recording time attachment, whereby the ordinates of the fluctuations of the velocity curves, automatically traced, can be measured, that any adequate knowledge of those high-wind gusts, which are really the most destructive to architectural structures, can be attained. These average velocities and the pressures deduced from them are very misleading for computing problems of stability to resist wind pressure.

Anemometer Velocity, Factor.—The factor representing the velocity of the wind propelling the cups is usually taken at 3, but a series of experiments by Mr. W. H. Dines for the Royal Meteorological Society has discovered that 3 is too high, and recommending that 2.10 be substituted for the 3 factor, as he finds that for a steady wind 2.27 is the nearest value, but for a gusty wind 2.00 is the most correct. *Quarterly Journal*, July 1892, p. 182.

Pressure deduced from Velocity.—The pressure = .005, velocity² × surface area. Messrs. Whipple and Dines recommend to be substituted for the New standard pattern of revolving cup anemometers .0029 instead of .005, and Prof. Marvin, U.S. Signal Service, having regard to the fact that the wind pressure is proportioned to the density of the air, adopts .004 representing a barometric pressure of 30in. The co-efficient .005 is generally known as Smeaton's.

Point of Application.—The point of application of the resultant of wind-pressure is usually taken at the geometrical centre, or centre of gravity of the surface, thus allowing for a uniform distribution of the pressure, which, for ordinary height of structures, may suffice while using 56lb. as the co-efficient. But when using a lower absolute pressure the centre of pressure will be raised in proportion as the pressure at the top of a high structure exceeds that at the bottom. For a method of solution in this latter case see the *Building News*, 1877, Vol. XXXIII. p. 215.

Altitude Increases Pressure.—An appreciable increase of velocity and pressure occur with increase of altitude for heights of about 100ft. and upwards above the earth's surface. The Eiffel Tower, Paris, was designed to resist a wind-pressure of 41lb. per square foot at the base, and of 82lb. per foot at the top.

The anemometer records of wind velocity at 994ft. upon the tower ranged from two to five times those registered at the meteorological station, 69ft. above the ground, and 1,640ft. distant from the tower.

Overturning Wind Formula.—The force of wind acting on a tower or tall chimney resolves it into the condition of a vertical cantilever fixed at its base, as it were, by its weight, and loaded along its length by the wind pressure, which is assumed as equivalent to a concentration of normal pressure at the centre of gravity of the

exposed surface. Then, with the wind blowing, say, towards the right horizontally, the maximum pressure produced at the leeward side = weight of the tower, &c., above the base or a particular bedjoint, as the case may be, + the moment of flexure producing compression—i.e., the unit normal pressure of the wind × exposed surface area × vertical leverage of the centre of pressure above the bedjoint or base. The maximum and minimum pressures are expressed as follows:—

The maximum pressure, P per unit area, at leeward side

$$= \frac{\text{Weight above base}}{\text{Base sectional area}} + \frac{\text{Moment of wind} \times \text{length of section.}}{2 \text{ Inertia of the base section.}}$$

Minimum pressure at windward side

$$P = \frac{W}{B-S} - \frac{M}{2I}$$

These two equations are general for any form of section, inasmuch as the values of the moment of inertia I of the particular section in question must be introduced; and they are applicable to any system of vertical and horizontal forces. The moment of inertia of a section is a quantity depending only on the form of the cross section, perpendicular to the line of stress, and is an element in the moment of resistance, m. If f = intensity of the extreme fibre strain, and y = the vertical distance of the fibre from the neutral axis of the section, then

$$m = I \frac{f}{y} \text{ and } f = \frac{m}{I} y$$

= the maximum intensity of stress in the plane of the extreme fibres. The position of the safe limit of the centre of pressure for any form of cross-section, when the pressure vanishes to zero along the windward edge, perpendicular to the direction of the wind, depends on the moment of inertia of the cross-section. The deviation d of the centre of pressure from the centre of gravity of the cross-section for a rectangular section is one-sixth of the diameter, i.e., the centre of pressure must not be nearer to the leeward side or edge than one-third of the diameter. The moment of inertia of a section is the sum of the products of its elementary zones or strips parallel to the neutral axis, and the square of the distance of their centres of gravity from the neutral axis. The neutral axis is perpendicular both to the direction of stress and also that of permissible deviation.

Values of Moments of Inertia for the following Sections:—

l = Length parallel to direction of stress, as of wind.
b = Breadth perpendicular to ditto ditto.

Square, $\frac{\text{Side}^4}{12}$, whether the axis or diagonal is in line of stress.

Rectangle, $\frac{b^3 l}{12}$.

Hollow square or rectangle: $(BL^3 - b^3 l) \div 12$
BL denote outside dimensions, bl = inside ditto.

Circle (solid), Radius⁴ × .7854.

Ditto (hollow), (Outer radius⁴ - inner radius⁴) × .7854.

Semicircle, Radius⁴ × .1098.

Ellipse (stress along l), $(\frac{B}{2} \times \frac{l^3}{2}) \times .7854$.
l = long diameter, b = short ditto.

Elliptic ring, $[(\frac{B}{2} \times \frac{l^3}{2}) - (\frac{b}{2} \times \frac{l^3}{2})] \times .7854$.

Triangle, base (parallel to neutral axis) × perpendicular ÷ 36.

Greek cross (Fig. 26), $(BL^3 + 2b^3 l) \div 12$.
(Neutral axis N.A. f is a lateral force tending to turn the figure about its neutral axis.)

To obtain the moment of inertia for other forms composed of rectangular elements, the moment of each zone-rectangle about its own neutral axis = (its breadth × its length)³ ÷ 12. Then the moment of inertia of each zone-rectangle about the neutral axis of the whole form = moment of inertia about its own neutral axis + (its area × distance² between neutral axis of zone rectangle and that of the whole form).

Deviation of Centre of Pressure from centre of Resistance.—The following are the limiting distances of deviations (d) of centre of pressure from centre of gravity and from leeward edge of maximum pressure in terms of diameter, or

side in the direction of stress, for usual forms of piers, chimneys, &c.

Rectangle or square $\frac{1}{2}$ diam. from leeward edge. Id.
Ditto (hollow *) $\frac{1}{4}$ to $\frac{1}{2}$ " " " "
Circle or ellipse (solid) $\frac{1}{4}$ " " " "
Ditto (hollow *) $\frac{1}{4}$ to $\frac{1}{2}$ " " " "

For a rectangular section B.S in the formulæ = lb, and I = $\frac{1}{12} b l^3$; since the moment of the wind M = total pressure H by height of centre of pressure above the base h. Then substituting these values in the formulæ—

$$P = \frac{W}{lb} + \frac{6Hh}{b l^2}$$

Since by the parallelogram of forces the wind-force H : weight, W : is the permissible deviation (d) of centre of pressure from the centre of gravity of the cross-section to h, height of the centre of wind-pressure above the base. Then, as the products of the extremes and of the means are equal—i.e., the wind-pressure H by height of its centre h = weight by deviation d. Hence, substituting these values in the last formula gives—

$$P = \frac{W}{lb} + \frac{6W \cdot d}{b l^2}$$

This formula requires only the most accessible quantities in a simplified form for solution in conformity with the principle of stability of the middle-third—i.e., the deviation (d) = $1/6 l$.

(To be concluded.)

THEATRES.—XIV.

By ERNEST A. E. WOODROW, A.R.I.B.A.

FIG. 1 is the plan of the grand staircase of the Grand Opera House of Paris. This staircase is one of the chief features of the building, and it occupies a space nearly as large as the auditorium. As is well known, M. Charles Garnier was the architect, and the building was erected between the years 1861 and 1874. In Fig. 2 is shown the arrangements of the entrances of another Parisian theatre—the "Châtelet"—built in 1861, from the designs of M. Davioud, the architect. The famous old theatre, La Scala, of Milan, is a marked contrast to the Grand Opera of Paris in respect to the magnificence of its approach staircase. (Fig. 3.)

There is a similarity in the plans in Figs. 4 and 5—the Grand Theatre, Bordeaux, and the Theatre Charles Félix, at Genoa. The former plan shows two levels, the latter the ground level only.

At the Theatre Royal, Turin (Fig. 6), the approaches are under the auditorium—an arrangement which is being adopted by the architect in the new Municipal Theatre, Amsterdam, the plans of which are reproduced in this year's volume of the *Transactions* of the Royal Institute of British Architects.

I have reproduced these series of plans to illustrate that theatrical architecture is not what it was, as far as this country is concerned, nor can it be where a national theatre is not supported by the nation. The plans speak for themselves. There is much, no doubt, that is grand and imposing in these plans; the careful student will also find that in detail there is, however, much that is defective, and sometimes even dangerous, in the planning. Although we may regret the departed grandeur, we may comfort ourselves with the thought that the modern staircase, "delivering directly into the street," is an innovation made for public safety.

To turn now to the rules and regulations governing the forms of staircases—I must leave the consideration of materials to the time when I shall have to describe the construction of the whole building.

The London County Council regulates the staircases in London theatres by this rule, which I quote now in full:—

"Every staircase for the use of the audience shall have solid square (as distinguished from spandrel) steps of York or other stone, or fire-resisting materials, to be approved by the Council, with treads not less than 11in. wide, and with risers not more than 6in. high, without winders, in flights of not more than 12 or less than 3 steps each.

"The treads of each flight of steps shall be of

* The ratios for hollows are approximations for ordinary and mill chimneys, towers with thin walls, &c. The limiting line of deviation, d, is perpendicular to the direction of the overturning force.

FIG. 1.

FIG. 2.

FIG. 3.

FIG. 4.

FIG. 5.

FIG. 6.

uniform width, and be pinned into brick walls at both ends.

"The several flights of such steps shall be supported and inclosed upon all sides by brick

walls not less than 9in. thick, to be carried down to the level of the footways.

"No staircase shall have more than two flights of 12 steps each without a turn.

"All landings shall be 6in. thick, be square upon plan, and have brick arches 9in. deep turned under them in the middle of such landings.

"Every staircase shall have a roof of fire-resisting materials to be approved by the Council.

"A continuous handrail shall be fixed on both sides of all steps and landings, supported by strong metal brackets built into the wall.

"Such handrails shall be chased into the walls, where the thickness of the walls will permit, but in all cases where the flights of steps return, the newel wall shall be chased so as to allow the handrail to turn without projecting on the landing."

I have already dwelt upon the various points which refer to the form or plan of the staircase which are detailed in this regulation, two other points, however, should be rigidly observed. The last flight of every staircase should be towards the street, and there should be an exit immediately facing the foot of each staircase. It will be observed that in the diagrams illustrating this article such an arrangement is not always carried out.

The staircases in Austria must be so placed as to be easily found, and close to the tiers or galleries; a provision, the benefit of which will be understood from the remarks I have made in my last two articles, when commenting on staircases; in London the rule is to have the exits, one on either side of the tier. The width required for staircases in Paris must not be less than 4ft. 10in., commencing at the highest level, which has to be increased in proportion on each flight to the number of persons using the staircase. This rule suggests that the staircase is entered at more than one level, which is certainly most undesirable, and sometimes even dangerous. A further rule confirms this belief, as it stipulates that every theatre shall have at least two staircases entirely devoted to the use of the audience, and independent of each other, and that these staircases shall communicate with each storey, and lead out into the street. This arrangement is not permissible in London, nor is it in St. Petersburg, for there it is enforced that staircases are not allowed which have direct communication between the corridors of the tiers or from the interior of the auditorium to the tiers.

These rules, however, should in no case prevent the formation of a "pass" staircase, to be used by the manager for the convenience of supervising the house; such a communicating staircase is also of the greatest value to the fireman, both in the performance of his ordinary duty and in cases of emergency.

In New York the openings to the staircases must be equal to the staircases themselves, and although the staircases must, as a rule, be inclosed in brickwork, the staircase to the first tier or dress circle, may be left open on one side, but in no case may a staircase be left open on both sides. When straight flights of stairs return directly on themselves a landing, as in London, of the full width of both flights without any steps must be provided, and stairs turning at an angle must have a proper landing at the turn without winders. In staircases where two side flights connect with one main flight the width of the main flight must be equal to the aggregate width of the side flights. The rise of the steps in New York may be 7 $\frac{1}{2}$ in. and the tread 11in. In circular or winding staircases the width of the tread in the narrowest part must not be less than 7in. There is undoubtedly a certain danger in "circular or winding staircases," and it is a matter of surprise that the New York regulations, which are otherwise so comprehensive and complete, should permit such an arrangement. In all the foregoing regulations handrails are stipulated as requisite on both sides of all flights of steps.

In a paper of mine printed in the BUILDING NEWS, 25th of last March, I said that I believed the abolition of the grand staircase was due to the custom of sinking the stalls below the street level, and placing the dress-circle on the street level. In the same paper I drew attention to the plan so frequently adopted by Mr. Phipps of placing two staircases passing one over the other within the same containing walls. This is a valuable economy of space. Diagrams of this arrangement were published in the above-mentioned issue of the BUILDING NEWS.

The city council of Glasgow accepted at their last meeting a portrait, by Sir Henry Raeburn, of the late Lord Provost Mills.

TWO EXHIBITIONS IN BLACK AND WHITE.

DURING the past few days two very different gatherings of examples of contemporary draughtsmanship have been opened to public inspection, and both, to the lover of artistic work, may be said to have very special interest, particularly to those who know how to use the pen or quill. The more notable of the two exhibitions is that held in Barnard's Inn Hall, Holborn, and consisting chiefly of the marvellous series of original drawings for Pablo de Segovia, by Daniel Urrabieta Vierge, the celebrated Spanish illustrator, who, working in Paris since 1869, first made a name in "Le Monde Illustré" and "La Vie Moderne," thereby actually founding, by his example, a new school of delineation, producing work full of freshness, vigour, and quaint humour as clever as need be, though few of Vierge's followers have been equal to his masterpieces. These are to be found, undoubtedly, in the famous designs with which he astonished the artistic world ten years ago, when Messrs. Bonhôte published the picturesque story of "Pablo de Segovia, the Spanish Sharper," by Francisco de Quevedo-Villegas. These are the drawings now on view in Barnard's Inn Hall, and Mr. Fisher Unwin, the well-known publisher, has just produced an English translation of the same romance, with enlarged reproductions of the original series, together with about twenty new pictures by Vierge, who, with great perseverance, has learned to draw with his left hand since the book first was issued, when a stroke of paralysis laid him low, depriving the artist of his speech and use of his right hand. The episodes in "Pablo" furnish endless subjects of the "Don Quixote" type, for the illustrator, with a variety of characters and questionable incidents; but the tale itself of the "Gil Blas" school, is exceedingly minor and quite unworthy of such masterly illustrations, in spite of the fact that probably the caricaturist would, with difficulty, obtain more serviceable material for his character studies. We can only mention a few of these, as typical of the remainder. The Dinner scene, where Don Alonso and Pablo are seated at the table of the wayside inn, while on their journey to the University, is a drawing which shows Vierge's power over facial expression and elaborate care in accessory detail. The contrast between the habits at the table of the common folk and the exquisite bearing of the superior person seated bolt upright, with his dinner napkin pinned down over the soiled tablecloth, is capably rendered. The artist's appreciation of architecture is often to be noted, as in No. 25, where the façade of the University of Alcala de Henares is drawn with great exactness and feeling. The Spanish iron grille, seen in No. 28, where Don Alonso's housekeeper is going to church, is another example. This drawing shows the great care of the draughtsman, such as in the fabric of the comic old woman's stiff stuff dress, and it shows, too, his capability of expressing, in the fewest lines possible, the utmost amount of character. Only the nose, and cheek, and mouth of the dame appear in profile in front of her bonnet, and yet how entirely complete is the study of her face; we seem to know her at once, with her airs, and her graces, and spurious piety. For drapery, take No. 62, where Don Jordon stands quaintly looking over his shoulder, and see how much can be indicated by pure outline. The designs are often overcrowded, and sometimes Gillot's reproductions were too much reduced to do the originals justice, as in 59, "The Melée in the House of Pablo's Uncle." The general effect, too, of some of the pictures is spoiled by the masses of black used in drawing a figure, say, in the middle distance, while those to the front are simply in outline, thus avoiding all attempt at tone or light and shade. Although probably the idea was to draw special attention to the central figures, the relative values of true perspective are lost. "The Pastrycook's Shop in Madrid" shows a picturesque street corner (73), and a quaint interior beyond the opening. In judging Vierge's studies, it must be remembered that the scenes are presumed to be seen under a southern sun, and generally the effect is conventionally brilliant to a degree, not to say dazzling, the shadows being treated capriciously as decoration. The exhibition includes some first-rate miscellaneous drawings of other subjects, such as the Painters, Plasterers, and Donkeys at the Paris Exhibition in 1889.

Turning from Barnard's Inn, we may visit briefly the gallery of Mr. Mendoza in St.

James's, where the annual Black and White Exhibition is on view. Somehow, and we hardly know why, the collection scarcely seems so interesting as usual. There are so few decorative subjects, though we noticed Mr. P. H. Miller's "Cupid and Psyche—Death of the Butterfly," drawn in red with much grace and breadth of drawing, if not with any great originality. Mr. Vincent P. Yglesias shows "The City of Lincoln," with the cathedral dominating the town, in an almost ideal fashion, with the minor towers and gables of the streets grouping round 'midst the mists of evening-time, which lend an enchantment to the view. Mr. J. Fulleylove, R.I., takes us to Warwick, where, from the roofs, he shows us a bird's-eye view of the inner ward now forming the well-known lawn in front of the great hall. The same artist exhibits "Mola St. Carlo," "Trieste," and "Capo d'Istria." Miss Marian Logsdail shows fresh drawings of very familiar subjects, such as "Desdemona's House," "The Grand Entrance to the Ducal Palace and the House of Gold at Venice." Mr. Percy Wadham brings us home to "Eton Old Courtyard," and Mr. A. G. Thomas gives a careful drawing of the "Old Poultry Cross at Salisbury." Miss Elizabeth G. Vawdrey, too, in a homely study, shows the old pents and exterior steps to the ramshackle houses in Pin's-lane, Plymouth, with an honest love of old buildings; but to the painter, and, of course, the magazine or newspaper illustrator, these will have but little attraction, where most of the works shown have been, at one time or another, prepared for such uses. Mr. Walter Paget can draw, and he does. His honestly worked-out scenes from "Robinson Crusoe," in a different way, may well compare with Vierge's studies of character and power over points of detail. Mr. C. Whymper shows the "Champion Skater," full on, in a foreshortened position, very difficult to render without loss of action. Mr. Alfred East, always a powerful draughtsman, shows "Naples," and Mr. Melton Prior a "Trout Lake from Nipissing, Ontario." Mr. Caton Woodville, as capable as ever, sends "Natives Diving for Coin, Aden," while Mr. W. L. Wyllie contributes "Southend Pier," "Irene" and "Innocence" are refined studies, characteristic of Mr. Henry Rylands, whose work is familiar to our readers; and Mr. G. C. Haité shows a brilliant little waterside sketch of a Surrey village, well suited for reproduction.

RIGHTS OF WAY.

UNDER the above title an interesting paper on the legal aspects of this somewhat complex question was read at the ordinary general meeting of the Surveyors' Institution, on Monday evening last, by Mr. J. Douglas Walker, Q.C.

The author, for practical purposes, classed rights of way under three heads—viz., public rights of way, private rights of way, and, for want of a better term, Parliamentary rights of way. The first, he said, had their origin in the dedication by the owner of the soil of so much of the surface of the soil as the road or way covers to the public for the purpose of passing or repassing. Everyone was entitled to pass over the surface without let or hindrance; but the use of the road for any other purpose by anyone not the owner was a trespass. The case of "Henderson v. Duke of Rutland," recently decided by the Court of Appeal, was not mentioned by the author, but will readily occur to our readers as confirming his statements on this point. So much of the soil and to such a depth was dedicated to the public (or the authority representing the public) as was necessary for the purpose of keeping the road in repair and laying any necessary pipes, sewers, &c.; but the ownership remained with the owner of the subjacent soil, to whom the right of minerals, &c., below the road exclusively belonged.

A private right of way was simply the privilege of passing over the land of another, and in no way conferred any ownership on the grantee, although he was empowered to repair the way and keep it in a fit condition for his use, on the condition that the owner of the land might use it in any way he liked as long as he did not interfere with the rights of passage. If a man, for instance, gave a license to lay pipes through his land to a cistern, the grantee might afterwards dig to mend his pipes, and the grantor might not do anything, in the way of building on the land or otherwise, which would prevent such

access to the pipes. But it must be observed that a right of way is a right to pass only from one point to another fixed point along an appointed line. If the way be out of repair the grantee may repair it, but must not deviate from it. The owner of land to which a right of way is appurtenant can convey the right to the purchaser of his land. A right of way may be acquired by prescription, for which enjoyment without interruption for a period of twenty years is necessary. The user must be continuous, and during the whole term sufficient to carry to the mind of a reasonable person owning the servient tenement (or the land over which the way passes) that a continuous right was being asserted and might, if necessary, be resisted. But the right could only be asserted for the purpose it was originally intended, and evidence of user for one purpose was not proof of the existence of a right of user for all purposes. The public were entitled, in the case of a public right of way, to the user of the whole width of a road between the fences; but the dominant owner of a private way was only entitled to pass with the convenience to which he had been accustomed for his accustomed purpose, and could not, therefore, complain if the servient owner narrowed or widened the road, so long as so much of the centre of the road was left as was necessary for his passage.

An action for obstruction of a private way could be defeated by showing that a public right existed before the alleged private right came into existence. If the dominant tenement—i.e., that possessing the right of way over the servient tenement—be divided, as in the case of building land let in plots, the law was clear that (without qualifying words) the right passed to each owner of each part of the severed lands; but the circumstance that the distribution of the right would materially increase the burden on the servient tenement might, under some conditions, be a very strong reason for inferring that such a distributed right did not exist.

A right of way by Act of Parliament combined, in some respects, the characteristics of a public and private right of way. A railway company could use the whole of the surface of the land between their fences, but they could not grant a right of way on any of the surface, except for the purposes of their Act.

A discussion followed the reading of the paper, in which Mr. G. M. Freeman, Mr. W. Wright, Mr. S. B. Saunders, Mr. T. W. Wheeler, Q.C., and Mr. P. D. Tuckett took part, and the usual vote of thanks terminated the proceedings.

CHIPS.

Mr. Arnold Taylor, an inspector under the Local Government Board, held an inquiry at the local board offices, Argyle-road, Sevenoaks, on Wednesday week, as to the board's application for sanction to borrow £1,500 for laying out a pleasure ground and for works of sewerage and street improvement. Mr. J. Mann, surveyor to the board, exhibited and explained the plans.

Major Isaacs, F.R.I.B.A., was entertained at dinner at the Bridge House Hotel, London Bridge, on Monday night, and presented with a testimonial, in recognition of his services as Conservative member of Parliament for the Walworth Division of Newington from 1885 to 1892. The testimonial took the form of a tea and coffee service and silver salver, accompanied with an illuminated address on vellum, the value amounting to 150 guineas, and the subscribers including about 1,130 contributors of a shilling and less.

The Accrington town council decided on Monday to apply to the Local Government Board for sanction to borrow £10,000 for the erection and equipment of a technical school, and for £10,000 to purchase land for, and the establishment of, a central electric-lighting station, and for £1,400 for the purchase of baths and wash-houses.

The corner stone was laid on Saturday at Swindon for St. Mark's parish. Plans have been prepared by Mr. W. Whincop, of Stoke Newington, for a building estimated to cost about £4,000; the church committee resolved to erect one section of the building first, and the contract was let to Mr. George Wiltshire, of Swindon, at £2,200. The building will be of brick with freestone facings, and have a frontage to Maxwell-street of 58ft.

By permission of the Society of Antiquarians, the large (17ft. by 8ft.) ancient painting on oak of "The Judgment," recently discovered in Wenaston church, will be on view at the rooms of the society, Burlington House, for a week from Thursday, December 15th, in the evening of which day a paper on the subject will be read by Mr. C. E. Keyser, F.S.A.

WESTMINSTER ABBEY: THE NORTH TRANSEPT AS
RESTORED.

THIS drawing was exhibited at the Royal Academy last summer by Mr. John L. Pearson, R.A., the architect of the restoration, and it shows the new façade of the North Transept as finished a short time since from his designs. Sir Gilbert Scott, R.A., renovated the great portals. We gave a photograph of the new front on June 5, 1891, and the series of new statues by Mr. N. Hitch on April 10th of the same year. The autograph drawing of the transept, as altered by Sir Christopher Wren, was published by us, in fac-simile, on Oct. 26th, 1888, and a detail drawing of Sir Gilbert Scott's work will be found in the BUILDING NEWS for May 3rd, 1878. We have thus furnished so many particulars of this national work, that nothing remains here to add.

"FIRSDENE," BROMSGROVE.

THIS proposed house, designed to comply with definite instructions, is arranged on a very convenient plan, a special feature being made of the hall, in which a large bay window is contrived by the side of the fireplace, similar to those in the dining and drawing rooms. The complete set of general working drawings herewith reproduced show in detail the principal arrangements, one good point worthy of note being the isolation of the kitchen and offices by the introduction of a luggage-entrance, which really is the tradesmen's door. The walls of Bromsgrove stone in courses, with roofs covered with Colley Weston stone slates in scale with the rest. The chimneys are shown in brickwork. The general effect of the residence, as in old houses, depends upon its groupings and main proportions, the details being exceedingly simple. The staircase seems the least satisfactory part of the plan. Messrs. Bateman and Bateman, of Birmingham, are the architects.

"CHRIST IN THE MIDST OF THE DOCTORS,"
BY HOLMAN HUNT.

THIS glass mosaic work has been carried out as an altar-piece for Clifton College Chapel by Messrs. Powell and Sons, of Whitefriars, and is an exact reproduction of the celebrated oil-painting by Mr. Holman Hunt, the well-known painter.

ST. PAUL'S CHURCH, ADDESTONE.

A SUM of money having been bequeathed for the beautifying of the chancel of this church, it has been decided, in consequence of the disproportion of the present chancel, to entirely rebuild it in accordance with the design which we now illustrate, and which has been prepared by Mr. Theophilus Allen, F.R.I.B.A., of 3, Duke-street, Adelphi, and the work will be commenced as soon as sufficient funds have been subscribed.

BUILDINGS IN MAYFAIR.

AMONG the improvements and changes brought about in London street architecture during the last ten years, there is none more remarkable than the transfiguration of Mount-street, and it must be admitted that the Duke of Westminster, assisted by his surveyor, Mr. Eustace Balfour, is to be commended for the personal trouble he has taken, and the public spirit he has displayed in his successful endeavour to beautify this most fashionable quarter of London. Old smoke-begrimed Mayfair is gradually disappearing, and in its place is growing up a neighbourhood of picturesque streets. All these charmingly-designed buildings, whether they be shops, flats, or private houses, and which meet the eye at every turn, have in every case been submitted to the personal inspection of the duke before their erection, and his judgment in rejecting some designs and approving others is exemplified by the pleasing result. The buildings we illustrate to-day form one of the latest demonstrations of the vast strides London street architecture has made towards the picturesque. They are being erected by Messrs. Trollope, from the designs of Messrs. John Giles, Gough, and Trollope, and when finished, and the street completed, it will only then be able to appreciate the vastness of the improvement of the approach to Grosvenor-square from Berkeley-square, which till now has been a source of danger and difficulty. The whole block consists of eight private houses on a quadrant, now renamed Carlos-place, and a large building in Mount-street, with shops and offices on the ground floor, and four sets of self-contained flats over. The amount of practical thought and experience bestowed upon the planning of these flats is amply repaid in the result, as notwithstanding their size, and consequently high rental, they are already occupied, even before their actual completion. Each flat is self-contained on one floor, and is entered from a commodious staircase, with passenger lift into a large square-panelled hall, from which a wide corridor, 7ft. across, leads to all the principal rooms—viz., a smoking-room, 16ft. by 12ft., dining-room, 24ft. by 18ft., drawing-room, 24ft. by 18ft., dressing-room, 11ft. by 18ft., two bedrooms, 18ft. by 18ft., another bedroom and bathroom, and w.c., two servants' bedrooms, pantry, kitchen, larder, scullery, servants' w.c., wine and coal cellars, with service lift from basement. On the top floor extra accommodation is provided for men-servants, one room for each flat. The construction is fireproof throughout. The floors of the corridors and living-rooms are laid with oak, and the bedrooms with pitch-pine. The kitchens and offices have wood-block floors, and the walls are lined with white glazed tiles. The whole building is fitted with electric light, electric bells, and hot water. Decoratively and constructionally, it is as complete as possible. The houses are not in such a forward state, but several are already sold. Being "wedge shape," the difficulty in planning was not lightly overcome; but a satisfactory result has been arrived at by placing the entrance-hall front stair and back staircase on the "wedge" side, and slightly dovetailing one house into the next. The whole block, houses and flats included, is constructed externally in red brick, with Portland stone dressings.—J. E. T.

WRIBBENHALL CHURCH, BEDWLEY: LYCH-GATE.

THIS Lych-gate has lately been erected at the churchyard entrance of All Saints', Wribbenhall, which stands on the high road to Kidderminster. It is of oak, with shingle roof and wrought iron cross-finial. The cost was £90; the design by Mr. Thomas Gordon, Court Lodge, Sevenoaks; and the work executed by Messrs. Smith, of Broseley.

BROOK-STREET BOARD-SCHOOLS, CARLISLE.

THESE schools are the second of a series of schools that were arranged recently by the Carlisle School Board to be erected by their architect, Mr. T. Taylor Scott, F.R.I.B.A., of that city. They form a group of boys', girls', and infants' schools, all detached, and occupying an important site in the southern part of the city, almost in the centre of a rapidly rising locality of superior self-contained artisans' houses. Up to the present time the boys' and infants' schools have been completed and occupied, leaving the girls' school to be erected at the south end of the site, which will have a large playground and covered playshed, and out-offices along with the infants' school. The boys' school, on the west side of the site, has

a separate playground, with the caretaker's house overlooking it and part of the infants' school. Each school has been designed with a maximum of cubical and superficial area, and, having large windows and dual ventilation, the rooms are exceptionally cheerful and healthy, everything having been carried out with these objects in view. The schoolrooms, classrooms, and corridors are heated with hot air in addition to large open fireplaces, and the lavatory and all sanitary appliances are of the best and most modern description. The buildings have been erected with machine-made Cumwhinton red bricks, white polished Alnwick stone, and Westmoreland green slates, along with pitch-pine woodwork, stained and varnished, for the interiors. Arrangements are now being made by the Board for the erection of additional school accommodation at the western side of the city, in order to relieve the present overcrowded schools.

ST. PHILIP'S CHURCH, STEPNEY.

LAST week we gave the plan, elevations, and general sections of this large church. To-day we print a sheet of details illustrating the morning chapel, which forms one of the most elaborate parts of the building, with its central shaft supporting the graceful groining of the roof, which is contrived on a somewhat unusual plan. The drawings carefully show how this is managed in the sections, which are taken both ways. The spout from the piscina is one of the minor details about the church, which show the care taken by the designer over items which often are neglected. The drip to the spout is insured by the chase on its soffit. The orthodox plan for wastes from fonts, stoups, and piscinas, however, is that they should communicate directly with soakage pits in the earth, and not, as in this case, empty into the open air. Mr. Arthur Cawston, A.R.I.B.A., is the architect.

CHIPS.

The Charity Commissioners have just sanctioned a scheme for the removal of the Birmingham Blue-coat School from its present cramped and inconvenient site in the city to new buildings to be erected on a rural or suburban site, and to increase the accommodation from 250 to 400 children.

A presentation was made at Liverpool on Friday, at the offices of the engineer to the Mersey Docks and Harbour Board, of valuable silver plate to Mr. A. G. Lyster, assistant engineer to the Dock Board, in celebration of his approaching marriage, by the staff of the engineering department.

At a meeting held at Peterborough, on Tuesday, it was resolved that a fund be opened, to be called the Argles Memorial Fund, for the purpose of erecting a memorial to the late Dean of Peterborough in the cathedral.

The parish church of St. Lawrence, at Evesham, was reopened on Wednesday week, after having been restored and re-seated from plans by Messrs. Carpenter and Ingelow, of London. The stalls in the chancel are of oak carved by Mr. H. H. Martyn, of Cheltenham; those in the nave are of deal. The chancel has been extended 30ft. into the nave. The outlay has been £1,400.

A large timber fire broke out on Friday morning, the property attacked being situated at 59, St. George's-road, Southwark, and owned by Mr. G. F. Arney, timber merchant. The yard was 300ft. by 50ft., and the fire blazed for three hours with great strength. Fifteen steamers and two hydrants were set to work, but the greater part of the buildings and stacks was destroyed.

A board school in Great Junction-street, Leith, was formally opened on the 1st inst. The school board acquired Dr. Bell's School, and the building has been added to, from plans by Mr. George Craig, architect, of Leith. The school will give accommodation for 1,082 pupils, and the cost of the alterations and additions has been £8,000. Messrs. Kinnear, Moodie, and Co. were the builders.

At a meeting of the electors to the Disney Professorship of Archaeology, held on the 1st inst., at Cambridge University, Mr. William Ridgeway, M.A., now professor of Greek at Caius College, Cork, was chosen to succeed Canon G. F. Browne, whose term of office had expired, and who did not seek re-election. The duties of the professorship consist of the delivery of six lectures during each academical year on the subject of Classical, Mediæval, and other antiquities. The stipend is about £100 a year. He holds office for five years, but is eligible for re-election.

A chancel has just been added to the little church at Cell Park, Markgate. Mr. J. Brown, of Luton, was the architect, and Mr. Dunham, of the same town, the builder.

WAYSIDE NOTES.

THE Panama business is a revelation. The disclosures made must have been unexpected in every quarter. Interesting will be the course of events herein.

We have the *Foudroyant* back again; much use will there be in the old hulk, cut down some 20ft. by the German ship-breakers who bought it for firewood and for what better purposes there could be found for the old timbers. Some individuals appear to have lost no time in connection with this matter. Prince Henry of Prussia, "among others," has, I read, had an entire suite of furniture made out of the *Foudroyant*, other German notables having a share in the timbers of which she has been shorn. In this way poop, spar-deck, and bulwarks have disappeared down to the level of the main deck. However, the syndicate who purchased this old line-of-battle ship seem satisfied with their bargain. Endeavours will be made to pass the vessel under the bridges, and so place her in the river in a suitable position for exhibition. If found impossible to pass her under the arches, she will be taken for exhibition to Greenwich or some other part of the Lower Thames. A restoration back to Nelson's days is contemplated.

As I anticipated, the decision of the Chelsea Vestry to do without an assessor in the baths competition has proved obnoxious to competitors. As certain architects are bound not to compete, and others will object to compete, there will not be a great display of talent in this competition. It is a pity that the commissioners could not obtain the information required. It seems a simple matter, and for the sake of the success of the competition I should advise further endeavours in the direction of appointing an assessor.

Another Roman villa discovery has been made—this time near Cambridge. In a field close to the road between Swaffham Prior and Reach, and near the Cambridgeshire "Devil's Dyke," the foundations of a villa have been unearthed. As usual, the most prominent feature in the discovery is the suite of hot-air bathrooms with their hypocausts, with the small tile pillars *in situ*. Samian pottery, tesserae, &c., have been discovered in connection with this find. It is said that the site and the nature of the findings bespeak a house of some importance, the lord of the manor at Swaffham conjecturing that the Roman military officer in charge of the north end of the Dyke may have been domiciled here. I am glad to hear that the public are permitted to inspect the works of excavation now in progress. In some other discoveries of this nature a boorish selfishness has been exhibited by those who have, or imagined they have, the right over the finds made.

The interesting old organ in St. Clement Dane's Church in the Strand is about to be restored. The instrument was built about the year 1690, by the celebrated Father Smith. From long-continued usage the instrument has become completely worn out. A sum of £900 is to be expended on its restoration.

It would seem a thousand pities to spoil Kensington Gardens by a new railway running across these open acres. To speak more boldly, it would be an abominable and disgraceful undertaking, and it is pleasant to note that there are persons actively opposing any proposal of this nature, even at this early date, when danger only threatens in a distant manner. Respecting the proposed Clapham Junction and Paddington Railway, Mr. W. Gardiner, chairman of the Paddington Ratepayers' Defence Association, is taking active measures to assist in the protection of the Kensington Gardens. Anything that destroys the quietude and beauty of these gardens is a national, not merely a local, loss.

To some persons it would seem a boon to working men to be able to travel from Edmonton, and other stations on the Enfield branch of the Great Eastern Railway, to London and back for the sum of 2d. That it should be a condition of such ridiculously cheap travelling that the traveller should be astir early in the morning would also seem but reasonable and just. Contentment, however, is not to be found here even, an agitation having been commenced for cheap

2d. trains arriving at Liverpool-street at 8 o'clock instead of 6.43. An equal concession at the other end of the day is demanded.

A fairer arrangement would be a charge of, say, 4d. to 6d., for trains up to 8 o'clock in the morning, the 2d. ticket being only for the earlier trains, as at present. In all probability, when the Great Eastern Railway Company have completed their new station works at Liverpool-street—now getting on favourably—they will go into the question of workmen's trains yet more fully. When the chairman of the company alluded to the new additions at Liverpool-street at a recent meeting of shareholders, he particularly stated that an extension of the system of cheap trains for workmen was one of the improvements contemplated when the present station was enlarged.

The photo-tint that you gave last week of the porch of St. Gilles Church, Caen, fine print though it is, scarcely gives the effect of this real architectural gem. As in many photos, the light on the portions of the building exposed to the light is quite lost, owing, possibly, to over-exposure of the original negative. It is the light, graceful character of the work about this grand old Norman porch that particularly strikes one coming fresh upon the scene. The true effect of the porch was given in a beautiful drawing by Mr. Herbert Railton in the *English Illustrated Magazine* for December, 1888. I have attempted a sketch of the work myself, but beyond getting a few notes of the charmingly *petite* detail that shows in your photo-tint, I did not make much of the job. It wants a master-hand.

Here is a high ideal, but a true and worthy one: "Life lies before us as a huge quarry before the architect; he deserves not the name of architect except out of this fortuitous mass he creates suitableness and durability; some form the pattern of which originated in his own soul." This may stand as a very good definition of a true architect.

How unprepared the London County Council is for the contemplated municipal building department may be at once seen from the suggested size of the staff to look after this proposed Works section of the Council's duties. The Council must swell out yet bigger before it attains to the large size and dignity which appears to be one of the principal, if not the chief, end and aim of its members.

I trust we may not have a hard winter this year, as much distress is threatened, and great hardship and suffering probable among the really poor. As far as regards the building trade, we get along all right until the bricklayers stop, and the other trades are hindered in consequence. Already frosts have caused temporary stoppages, and there seems an impression abroad that we may have frost of some duration. Those who give ear to an old saying with regard to berries and frost should believe that there will be very severe frosts indeed this season. Never have I seen more berries. They are in abundance on all trees and bushes in every hedgerow, and grow in masses in the winter woodlands.

"Taffy was a Welshman, Taffy was"—well, a promoter of competitions in which the architects who responded to his invitation certainly came off second best. The Royal National Eisteddfod of Wales has issued conditions of competition for plans, specifications, &c., of a pavilion for its next year's meeting, which are a trifle one-sided. The pavilion is to be erected on Ynysangharad (corner) Field, Pontypridd. The plan is to show, and the pavilion to contain, seats for 20,000 persons. A builder's estimate is to be sent with the design, for the amount of which the owner of the design (provided his design will be selected) will be bound to erect the pavilion. The names of two substantial sureties to be sent with the plans and estimates, who will enter into a bond jointly with the contractor, to erect the pavilion for the amount of the estimate and within the time specified. Plans, specifications, and estimates must be in the hands of Mr. H. S. Davies, hon. sec. Pavilion Committee, Town Hall Chambers, Pontypridd, on or before 1st January next. *The remuneration of the architect is to be included in the estimate, and paid by the builder, and the committee do not bind them-*

selves to accept the lowest estimate or any of the plans that may be sent in. I wonder how many designs the committee will get! GOTH.

OBITUARY.

DR. WERNER VON SIEMENS, the well-known electrical engineer, and younger brother of the late Sir William Siemens, died in Berlin on Tuesday, aged 76 years. Under the auspices of the Prussian Government, he invented and perfected various processes of galvanised gold and silver plating. He also devoted himself to constructing and developing the systems of electric telegraphy, the most important of the latter being the first great telegraph line on the Continent, that between Berlin and Frankfurt-on-Main, which he established in 1849. Six of the Atlantic cables, as well as many other submarine systems, were laid by Messrs. Siemens Brothers Limited, to the formation of which company Dr. Siemens greatly contributed. He was the inventor of the pneumatic-tube system, and, in 1867, of the dynamo, by which electric lighting has been rendered a practical possibility, and was also the first person to work out commercially the invention of electric railways.

The death is announced of M. Pierre Galland, who was born in 1822 at Geneva, his father being an artist and a master workman in gold. At eighteen he entered the *atelier* of Labrousse, and two years later that of the painter Drolling, working at architecture three days in the week and at painting the rest of the time. Galland wrought in the whole field of decorative design, painting meanwhile a number of portraits merely to gain a living. He gradually became known as one of the most accomplished artists of his time to the decorators then famous in Paris, and at the *Salon* of 1843 they united in designating him to organise the projected works. Galland would have risen quickly to fame in Paris had he not received an offer to decorate the interior of a palace which a rich Armenian was building at Constantinople. Galland accepted the commission, which occupied him during eighteen months. On his way home he studied in Naples, Rome, Florence, Venice, and Genoa. On returning to Paris, in 1853, he opened an *atelier* for himself, and since 1873 he had been Professor of Decorative Art at the Ecole des Beaux Arts, and since 1877 Director of the Gobelins.

CHIPS.

The Highgate Museum of Sanitary Appliances, established by the Hornsey local board, was formally opened by the Lord Mayor yesterday (Thursday) afternoon. The museum, which has been organised by Mr. T. De Courcy Mead, surveyor to the Hornsey board, was described in our last issue, p. 795.

Mr. Havard Thomas has prepared a model of the statue of Edmund Burke, which he is executing at the request of Mr. W. H. Wills for presentation to the city of Bristol. Burke is depicted as he is addressing a public assembly. The figure will be cast in bronze, and is to be 8ft. in height. It will stand on a granite pedestal about 10ft. high.

The two new branches for the National Provincial Bank of England at Hampstead and at Landport are both being warmed and ventilated by means of Shorland's patent Manchester stoves, with tiled sides, the same being supplied by Mr. E. H. Shorland, of Manchester.

A large illuminated turret clock has just been erected in St. Luke's Church, Kingston-on-Thames, with four 7ft. skeleton cast-iron dials, filled in with white opal glass; also an index dial in clock chamber, by which to adjust the outside hands, and an automatic gas apparatus attached to the clock for turning on and off the gas, all of which have been made and fixed by Messrs. Potts and Sons, of Leeds, who have in hand a turret quarter-chime clock for the corporation of Richmond, Surrey; one for Colne town hall, Lancashire; one for the Catholic Cathedral, Cambridge; and other important works.

The corporation of Salisbury recently invited competition by the leading turret-clock makers for a large clock to be placed in a new clock-tower now being built in Salisbury, and the firm of John Smith and Sons, Midland Clock Works, Derby, has been selected to carry out the work. The clock will be constructed with all the latest improvements generally to the designs of Lord Grimthorpe. The time will be shown on four illuminated dials, each 5ft. across. The pendulum will be compensated, and will weigh about 3cwt. The same firm are making St. Paul's Cathedral new clock under Lord Grimthorpe's supervision.

THE BLOUNT DOOR SPRING AND CHECK.

THE novel feature with regard to this door spring and check, which is made and introduced by Messrs. Charles Winn and Co., of Granville-street, Birmingham, lies in the fact that there are no external rods or cylinders, which disfigure the patterns already offered by some makers; but the article is of a compact form and agreeable to the eye, while the door opens with such slight resistance that one would scarcely notice it—in marked contrast to the excessive force required to open doors to which other makes of door checks are attached. This check is noiseless in working, and the checking power is regulated with a small thumb-screw, by which the door

can be adjusted to close at any speed required, although slamming is entirely prevented. The arms are connected by means of a ball joint, which prevents the motion from binding in case the door drops on its hinges, or swings out of line; and there is a screw adjustment provided by which the length of the arm can be varied to suit mouldings of varying projections. The closing or spring power can readily be increased, decreased, or removed entirely without disarranging any part of the check. The check is sold in four sizes—for light, ordinary, heavy, and extra heavy doors.

THE SOANE MUSEUM CURATORSHIP.

WE are informed that a number of applications have already been sent into Mr. F. A. Eaton, the secretary to the Royal Academy, by candidates for the appointment of curator to Sir John Soane's Museum, and that the last day for receiving applications is the 31st December. A permanent appointment will probably be made early in January. The conditions are peculiar. Under the private Act governing the Museum, the appointment is vested in the President and Council of the Royal Academy, who must proceed to an election within three months of the occurrence of a vacancy, the conditions being that the curator shall be an architect of English birth, and not less than 25 years of age, who shall have distinguished himself in architecture, or carried off some Academic prize. The salary attached to the post is £300, clear of all deductions, with residence. The trustees of the Soane Museum have, however, the power of making a temporary appointment, and they have chosen Mr. Wyatt Papworth, F.R.I.B.A., who has entered upon residence. No better permanent appointment could be made for the post than that of Mr. Papworth, who has edited every edition of Gwilt's "Encyclopædia," published since 1864, and also the "Dictionary of Architecture"; he has also published many papers on the bibliography of architecture, and is well read in its classics and archaeology. Mr. Papworth, whose portrait was given in the BUILDING NEWS for June 6, 1890, represents in the third generation the traditions of his profession, as his grandfather was one of the architects, builders, and decorative plasterers of the closing years of the eighteenth century. He has been a Fellow of the Institute of Architects for 32 years, and is now serving for the third or fourth time on its council. Since the Soane Museum has been opened four days a week for six months in the year, from February to August inclusive, it has been visited by a larger number of persons, and last year the attendances reached the highest point, about 2,000. It is singular to note that since the museum was opened on the death of Sir John Soane, Jan. 20th, 1837, a period of

nearly 56 years, there have been but three curators, George Bayley, Soame's pupil and assistant, 1837–60; Joseph Bonomi, the Egyptologist, 1860–78; and Joseph W. Wild, the Orientalist and decorator, who died a month since.

CHURCH WALL DECORATION.

THE fine church of St. Peter's, Plymouth, the new nave of which has been erected from designs by Mr. G. H. Fellowes-Prynne, F.R.I.B.A., is about to be decorated by a series of ten panels, to fill the spaces over the arcades, illustrating incidents in the life of St. Peter. These panels will occupy the place of the triforium, below the clerestory, and have been painted by

Mr. E. Fellowes-Prynne, of 8, Aynmore-road, West Kensington. This gentleman has now completed the panel to occupy the space over the central arch on north side of nave. The subject represents St. Peter confessing Jesus to be the Christ. The apostle kneels before Our Lord, who holds out the keys; on each side are groups of the Disciples. The painter has here taken the Gospel narrative of Matthew xvi. 16. Other panels illustrate St. Peter's call, his walking on the sea, his denial, condemnation of Ananias and Sapphira; healing; his vision, and other incidents recorded in the Acts. Above the chancel arch, which is the work of the late Mr. Street, who designed the chancel, a considerable wall space is left, which is intended to be filled by a painting representing the Church Triumphant. The spandrels are occupied by tiers of kings and prophets of the Old Testament, while above the apex of arch in a pointed aureole stands our Saviour. His head invested with a nimbus, holding a banner and cross; at the sides are figures of the Blessed Virgin, Joseph, St. John the Baptist, &c. The Twelve Apostles, saints, and martyrs fill up the lateral spaces. The Holy Innocents are at the foot of the aureole, while above angels and archangels and a crowd of the seraphic host appear in serried ranks on a gold ground. The symbols, straight and flamboyant rays, and other decorative features add to the expressiveness and splendour of the composition, which is well balanced and in excellent perspective. In the painting of the panel subjects the artist has adopted strong colours, having in view the position above the eye and the light, the ground being of gold imitating mosaic.

Mr. W. H. Stanley, architect, of Trowbridge, has received instructions from the Right Hon. Lord Donington to prepare plans for various alterations and additions to the residence known as Farleigh Hungerford Castle, in the county of Somerset.

On Saturday afternoon 50 students attending the architectural and building construction classes of the Glasgow Technical College (Mr. Charles Gourlay, lecturer) visited Hawkhead Asylum. The party were conducted by Mr. Crawford, clerk of works, through the main portion, which is just being built, the farm-stead, which is nearly finished, and finally inspected the quarry on the estate, whence some of the stone is being obtained.

The corporation of Manchester are about to apply to the Local Government Board for a provisional order enabling them to borrow £60,000 for the purpose of open spaces. The following is an estimate of the requirements in each district: Gorton, £7,400; Openshaw, £5,000; Clayton, £9,000; Newton Heath (Gaskell-street), £1,400; Crumpsall (Oak-road), £12,000; Gibbon-street, £10,500; Prussia-street, £500; Birch Fields, £4,159; Harpurhey, £2,470; Bradford, £1,010; Mount-street and Raven-street, £1,694; St. Michael's, £1,436; Phillips Park, £1,750—total, £58,319.

COMPETITIONS.

BEXHILL.—In the competition for the new local board offices, the assessor has selected the designs of Mr. H. Ward, architect, of Hastings.

BIRMINGHAM.—The Birmingham City Council took on Tuesday the first step towards the provision of a new Municipal Technical School, by authorising the purchase of a site in Suffolk-street, at a cost of nearly £12,000. About a year ago the Corporation took over the industrial department of the Midland Institute, and added to the curriculum and appliances. The rooms are now overcrowded with students. The Technical School Committee were authorised to obtain designs for the erection of a central technical school, from competing architects, submitting one design to the Council for acceptance, with an estimate of the cost of carrying it out, and for this purpose to employ a consulting architect.

MYTHOLMROYD.—In the recent open competition for schemes for dealing with the sewage of Mytholmroyd, Yorkshire, the three premiums of £60, £25, and £15 have been awarded as follows:—1st, Mr. F. Beesley, Westminster; 2nd, Mr. W. H. Thomas, Westminster; 3rd, Messrs. Savage and Davies, Sheffield.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

LEEDS AND YORKSHIRE ARCHITECTURAL SOCIETY.—The lecture session of this society was opened on Monday night by Mr. A. Keen, of London, who gave an address on the subject of "Vaulting." Mr. Bulmer, the president, was in the chair. The lecturer set out with an expression of the fear that the casual observer, in looking at an ordinary building, never realised the extent to which the vaulting over his head governed the plan and general disposition of the building. But when anyone came to design such a structure, the importance of the vaulting impressed itself upon him with startling force. Mr. Keen next traced the origin and early history of the arch in various countries, particularly in Egypt, after which he passed on to notice the use which the Chaldeans made of the arch and vaulting. In Roman times the interest in vaulting consisted chiefly in the scope for artistic work which its surface presented. In due course the early history and the uses of the flying buttresses were traced, and its importance in connection with groin vaulting was mentioned. The pointed arch had, observed the lecturer, exercised more influence on the groin vault than anything else. Indeed, many modern achievements in the way of vaulting would have been quite impossible without the pointed arch. The actual construction of vaulting in modern work was illustrated, and a comparison made between English and French vaulting. In conclusion Mr. Keen touched in detail upon fan tracery vaulting, and described the ornamental bosses in use in the Gothic vault.

YORK ARCHITECTURAL ASSOCIATION.—The annual dinner of this association was held at the White Swan Hotel, Pavement, on Thursday evening, the 1st inst., Mr. W. Hepper presiding, and Mr. W. Pollard being in the vice-chair. Those who took part in the post-prandial proceedings were the gentlemen named, and Messrs. H. Perkins, Hirst, Parkin, Yeomans, Fellgate, Dow, Clappole, and Milburn.

The Duchess of Albany distributed, at the Chelsea Town Hall on Thursday evening last, the prizes and certificates to the students of the science and art classes carried on in connection with the Polytechnic Institute for South-West London, at the Onslow College, King's-road, Chelsea. Lord Chelmsford presided.

A boys' school at Frodsham was opened on Wednesday week by the Bishop of Chester. It occupies the site of the old grammar school, but covers a larger area. The floor is covered with pitch-pine blocks on cement concrete bed. The main building is 70ft. by 26ft., and 20ft. 3in. high. Internally the school is lined with glazed brick to the height of 5ft., above which the walls will be decorated in duresco paint in tints. The premises are built of local brick, with Rusabon patent terracotta dressings, specially made to the architects' drawings. The cost, exclusive of furniture, is £1,150. The school has been erected by Mr. Thos. Davies, of Frodsham, from designs by Messrs. C. E. Linaker and S. Davies, architects, Frodsham, Mr. John Davies having acted as clerk of works.

Building Intelligence.

JUNIOR CONSTITUTIONAL CLUB.—This building, which was opened for the use of members last Monday, occupies the site of four houses in Piccadilly between the Badminton Club on the east, and Sir Julian Goldsmid's house on the west, with a superficial area of about 11,000ft. The basement contains a kitchen, 58ft. by 24ft., with larders and other offices surrounding it. On this floor also are the wine-cellars and servants' hall, and rooms for men-servants, as well as a considerable space devoted to steam boilers, pumps, &c., for the purpose of supplying steam for kitchen, &c., and for heating the house. On the mezzanine floor over, which is on the level of Yarmouth-mews, are arranged stewards' offices, and rooms for the upper servants, still-room, and members' lavatories, &c. The ground floor is raised about 7 feet above the level of Piccadilly, and contains in the front a smoking and morning-room 85ft. long by 28ft. wide, 22ft. high, divided by white marble columns with deeply recessed bays. At the back is a billiard-room with three tables. The entrance-hall is placed at the east end facing Piccadilly, with an entrance-door of Ross of Mull granite flanked with large Shap granite columns. From this, by a flight of marble steps a spacious vestibule is entered, off which is a reception-room. The vestibule opens into an inner hall 44ft. by 30ft. divided by large red marble columns which mask the staircase leading to the first floor. This staircase is 10ft. wide, entirely of white marble, with Waulsort marble balusters, while the walls of the whole of this, as well as the inner and outer halls and the wide vestibules on the principal floors are lined with Waulsort and clouded vein marble. On the first floor the staircase leads to a central landing 24ft. by 20ft., off which is the morning-room, 72ft. long by 25ft. wide, with the back part raised some two or three feet. The grand dining-room is L-shaped, the front portion with deeply-recessed bays being 85ft. by 28ft., and 20ft. high. The returned portion of this room is 60ft. by 25ft., giving a total length of 145ft., and is so arranged that it can at any time be used for public meetings. On the second floor is a library 62ft. by 25ft., fitted up all round with bookcases, and in addition are drawing, house committee, and dining, card, and private billiard rooms, and rooms for the secretary and staff. On the three upper floors have been arranged between sixty and seventy bedrooms, for the use of members, and rooms for servants. Throughout the building marble has been largely used; the principal portions of the building, and the whole of the internal fittings and ceilings, have been designed by the architect. The whole of the building throughout, including the roof, is of fireproof construction, by Messrs. Homan and Rodgers. The exterior facing Piccadilly has three boldly designed bays with gables over, the whole front being faced with white Norwegian marble with Portland stone used in the dressings and cornices. The design of the façade is Italian Renaissance, freely treated. Colonel Robert W. Edis, F.S.A., is the architect. The general work has been done by Messrs. Bywaters and Sons, the ornamental plastering work by Messrs. Jackson and Sons, the elevator and lifts by the American Elevator Co., the whole of the marble and stone front having been executed by Messrs. Burke and Co. The principal rooms are fitted with electroliers, by Messrs. Rashleigh, Phipps, and Dawson. We illustrated the plans and view of the clubhouse in our issue for October 10, 1890, and after an inspection of the building we may say that it is one of the most sumptuously furnished and conveniently planned clubs in London, skilfully contrived without any meretricious detail.

PATRICROFT.—The foundation-stones of a new workhouse for the Barton-upon-Irwell Union were laid on the 30th inst. The building when completed will give accommodation for 500 inmates, with provision on the grounds for further extension when necessary. The workhouse will be built in sections, so as to provide for the housing of the inmates without removal to other premises. The first section will consist of the aged, infirm, and able-bodied inmates' ward, and the administration block. The contract for this first section has been let to Messrs. Southern and Sons, of Salford, at a cost of £16,250, and is to be completed by the end of April next. When finished, the remainder of the buildings will be let, and it is expected

the total cost will be about £30,000. Messrs. Mangnall and Littlewoods, of Brown-street, Manchester, whose design was selected in competition, are the architects for the building. The building will be plain yet substantial in character. The administration offices, which contain the master's residence at the front, with the dining-room near to, will be used for Sunday services, and will be heated artificially.

RAWMARSH.—The new offices of the Local Board on Rawmarsh-hill, Parkgate, were formally opened on November 30. The new buildings are in the Renaissance style. The facings are of pressed bricks, with local stone dressings and mouldings. The main entrance is in the centre of the front. To the right is the clerk's office and a strong room. To the left is the collector's office, while at the end of the hall is the surveyor's office. The principal rooms upstairs are the board and committee-rooms. Adjoining the offices, and connected therewith by a passage, is a commodious caretaker's house. The total cost of the buildings and furnishing (exclusive of site) is about £2,050. The contractors have been: Mason and brickwork, Mr. W. H. Trehern, of Parkgate; joiners' work and part of furniture, Mr. John Tradewell, of Parkgate; and encaustic tiles, Messrs. Minton, Hollins, and Co. Mr. J. Platts, of Rawmarsh-hill, was the architect.

SHEFFIELD.—The new police-station at Neepsend is ready for occupation. It is situated at the corner of Burton-road and Hicks-street, and is carried out in pressed red bricks, with stone dressings. The chief elevation is broken up by two gables, one of which is above an arched gateway leading into the parade ground. The buildings consist of a charge office and search-room, with two cells, and lavatory and closet accommodation for officials and prisoners. There are also two dwelling-houses for police officers abutting upon the station yard; but the charge office and cells are self-contained, and completely shut off from the dwelling-houses, as well as from the adjoining street, while further cell accommodation can be added when required, without any rearrangement, and at a minimum of expense. The buildings have been designed and carried out by the borough surveyor and his staff at a cost of about £1,650, the contractors being Messrs. Walker and Slater, of Derby.

CHIPS.

Some extensive warehouses which have been in course of erection for the last four months in Drake-street and Richard-street, Rochdale, for the local Canal Company, are now completed. The work, which has been in the hands of Mr. Thomas Taylor, of Rochdale, was inspected on Wednesday week. The premises cover an area of over 3,000 square yards, and will be fitted up with the most modern machinery for hoisting, lifting, loading, and unloading. There is accommodation for 15,000 bales of cotton, and the whole process of loading and unloading can be carried on under cover.

Mr. Tate has finally accepted Sir William Harcourt's offer of the site at Millbank for his collection of modern pictures, which he gives unconditionally to the nation.

The trustees under the will of the late Alderman Scott, of Burnley, have bought a site for a public park for the town. The amount available, with interest, for the purchase was between £15,000 and £16,000. The trustees have secured a plot of land at the west end of the town, part of the Hood House estate. It is about 16 acres in extent, and running through it is a well-wooded clough.

At the Manchester Consistory Court, on Friday, a citation was decreed for a faculty to insert in St. Mary's Church, Whalley, a memorial stained-glass window, designed by Mr. E. Burne Jones, A.R.A., and executed by Mr. William Morris in the place now occupied by a plain-glass window, at the east end of the southern wall of the church. A representation of the Good Shepherd will occupy the centre portion, with the figure of an angel on either side. At the base of the window will be verses 10 and 11 of John x.

Myrtle-street Baptist Chapel, Liverpool, has been closed for renovation and decoration. Messrs. Morton and Son, Bold-street, Liverpool, are carrying out the works.

In a letter to Tuesday's *Liverpool Mercury*, Col. C. O. Ellison, the first President of the Society of Architects, propounds a scheme for covering over a portion of Great Charlotte-street, between the markets of Liverpool, with iron and glass roofs. The subject will be brought under the consideration of the Markets Committee.

Correspondence.

CHRIST HOSPITAL COMPETITION.

To the Editor of the BUILDING NEWS.

SIR,—Before it is too late, will you allow me, through the medium of your large circulation, to suggest to the Council of Almoners the possibility of selecting at least ten names for this competition, and divide the premiums as follows?—No. 1, the execution of the work; 2, £400 premium; 3, £200 premium; and £100 each to the next six.

This would be more liberal to the profession generally, and give more employment to draughtsmen during the winter. I enclose my card, and remain—I am, &c.,
KUDOS.
(One who has applied to compete.)

BOROUGH OF KEIGHLEY HOSPITAL FOR INFECTIOUS DISEASES COMPETITIVE DESIGNS.

SIR,—In the BUILDING NEWS of the 2nd inst. you give illustrations of the first premiated design for the above, proposed to be erected by the corporation. Further particulars of this competition will, I have no doubt, interest your readers—more particularly the thirty competitors who forwarded designs.

The conditions issued by the corporation to be observed by the architects contained the following directions, viz.:

"No architect will be appointed unless his designs meet with the approval of the Local Government Board.

"Competitors to send descriptive specification with estimates of the buildings, which must not exceed £4,000.

"The following buildings to be provided, viz.—Administrative Department: . . . three hospital wards of 10 beds each; disinfecting rooms and apparatus; laundry, with necessary fittings; boiler-house, with boiler and chimney; mortuary; ambulance-house; and stabling for two horses."

The estimated cost of the buildings "must not exceed £4,000," and I take it the estimate accompanying the successful designs did not exceed this sum; otherwise they would (or should) have been disqualified. Bearing this in mind, it is exceedingly strange—to put it mildly—that after all the accepted plans, which should have been so arranged when submitted as to meet with the approval of the Local Government Board have, by order of the Corporation, been *entirely* rearranged, the typhoid-fever block *abandoned*, one story taken off the administrative block, the disinfecting apparatus, &c., not included, and other deductions made. The amended estimate of the accepted local architect is still several hundred pounds more than the sum fixed by the Corporation for the complete scheme, and upon which the competing architects based their designs.

It is admitted that the cost of the accepted designs has been reduced some £1,500, and still remains considerably over the sum fixed by the conditions, and the committee must have known when they accepted the plans that it was utterly impossible to carry out this scheme for the sum stated.

Some 30 sets of plans were submitted, and at a reasonable estimate must have cost £600 to produce. After this trouble and expense, it is surely not too much to expect to be treated fairly, and that the terms of the competition should be reasonably adhered to.

I should say that no professional assessor has been appointed by the Corporation in this matter.

—I am, &c.,

COMPETITOR.

DRAINING AND PLUMBING SPECIFICATION.

SIR,—The motive that has actuated Mr. Baker in writing his specification is in itself commendable; but his object is not likely to be attained unless he gives more trustworthy advice than he has in some cases. It is, therefore, necessary, in the interests of sanitation, to draw attention to a few errors.

In Clause 79 he specifies the mode of constructing a soil-pipe junction that is about as bad as it can be. Perhaps Mr. Baker will state why he requires the fall of the branch pipe not to exceed 10°; the fall cannot be too great, and should not be less than about 30°. Again, the form in which the branch pipe enters the main pipe, as shown

in Fig. 11, is bad in the extreme; when the branch is discharging it cannot fail to foul the opposite side of the main pipe, and when the main pipe is discharging, the lower angle of the junction. The branch pipe should join the main pipe in exactly the same way as two pairs of railway metals at a switch, the bore of the pipe being exactly maintained throughout, and without any angle whatever.

In Clause 92 Mr. Baker gives a table showing when a 3½ in. and when a 4 in. soil-pipe should be used. Can he give any reasons for recommending either of these sizes in the particular cases? The same size pipe that does for one closet will do for a dozen; there is no reason for using a larger pipe. The total time during the day when any water-closet is actually discharging down the soil-pipe will (each discharge taking only a few seconds) probably not exceed a minute, and there is no probability of all the closets being discharged at the same moment. Even if this should occur the discharges would simply be following each other down the pipe at a short distance apart. A 3 in. pipe is large enough for any case, and is in all respects to be preferred to a larger size. What is the use of discharging, say, a valve closet, the diameter of the valve being 2½ in. into a 4 in. pipe? The tendency is to foul the pipe all the way down, whereas, were the same closet to discharge into a 2½ in. or 3 in. pipe, the water, &c., would fall as a piston down the pipe, and clear it as it goes. I know of a case where a 2½ in. soil-pipe was cut into after eighteen years' use, and was found to be bright and polished inside. Can the same be said of a 4 in. pipe? On the other hand, I once took out an old 4 in. vertical lead soil-pipe that was incrustated with hard deposit the whole length of the inside, reducing the diameter to less than 1½ in.

Clause 96 reads as though Mr. Baker recommends, or at least allows, long waste pipes. They should never exceed 4 ft. in length, and the shorter the better; they should be carried immediately through the external wall, and, if not on the lowest floor, discharged into a R.W. head and pipe. The size specified by Mr. Baker, 1½ in., is too large, and no trap should be placed at the outgo of the sink or lavatory basin. The effect of this trap is to retain foul water, destroy the power of the discharge, and to foul and finally stop the waste; on the other hand, if a 1 in. short waste without trap be used, and the are of the outgo of the sink or basin exceed the sectional area of the pipe (which is belled out at top), the water will be discharged at a good velocity and at full bore through the pipe, without leaving any deposit of soap, &c. Wastes should fall, and as much as possible, during their whole length, to prevent air being detained in the pipes, thus practically trapping them with the afore-said evil results.

The same applies to bath wastes, which Mr. Baker would have 2 in. or even 3 in. (!) diameter; 1½ in. is, I find, the best size for bath wastes, and this should not be exceeded. In all cases, whether w.c., sink, or lavatory, the sectional area of the outgo should exceed the sectional area of the waste, so creating a pressure on the water in the pipe, which will then run full bore, instead of dribbling down the sides as it usually does, depositing filth as it goes.

Turning a pipe back in the way shown in Fig. 19 is bad, and should only be resorted to when any other way is impossible. The direction should be straight from the pipe to the drain in an oblique direction with the flow, and at a tangent.

Clause 99 is also objectionable. Wastes should be discharged into the open air over the gully, and not connected by a side inlet under the grating.—I am, &c.,
BERNARD DICKSEE.
35, Queen Victoria-street, E.C., Dec. 5.

"CURIOUS ACTION BY AN ARCHITECT AND CONTRACTOR."

SIR,—In the "Legal Intelligence" of your last issue, and under the above heading, you state:—"Ultimately the defendant got another person to finish the house, which cost him double the money."

This necessitates a correction.

The defendant, after the dispute with plaintiff, instructed me to design a house, which has now been completed from my drawings and under my superintendence, and it was only a few days ago that I knew of other plans being prepared by the plaintiff prior to my being retained.—I am, &c.,
G. A. HUMPHREYS, Architect.

Mostyn Estates Offices, Llandudno, Dec. 5.

ECHO IN BUILDINGS.

SIR,—Re your references to above in last week's BUILDING NEWS, perhaps the following report, received by us a few days ago, and which, we may mention, is only one of many of a similar character we have received from time to time, may prove a solution in one way of the problem, how to do away with echo in buildings?—which, in this particular instance, is a board school in Bridgend, Glamorganshire, to which has been applied one of our latest improved patent self-acting air-pump ventilators, and four of our improved air-inlets.

"You may be interested to know that a school-room in which the reverberation, or echo, of the voices was so great as nearly to drive the teachers out of their senses, and which was under discussion as to whether it should not be abandoned, was, after an air-pump ventilator and four inlets were fixed, so improved as to be quite usable. This is an interesting case as regards acoustics."

We may state that we have not only found our system of ventilation improve the acoustics of certain buildings, but also the heating, which previously was defective.—We are, &c.,

ROBERT BOYLE AND SON, LIMITED,
Ventilating Engineers,
64, Holborn-viaduct, Dec. 5.

Intercommunication.

QUESTIONS.

[10907].—**Deadening Sound.**—I require a large quantity of sound-deadening material for putting between the joists of floor and ceiling below. I thought of nailing boarding to strips between the joists and depositing thereon small ballast or sand. Is there at a reasonable cost any better method or material for the purpose?—FUGARGE.

[10908].—**Glazing.**—What is the easiest and most accurate way of testing thickness of glass in windows after glazing?—W. A.

[10909].—**Orientation of Churches.**—Will any reader who knows of a noteworthy example of a chancel of any church in England being arranged otherwise than to the east mention the church and circumstances concerning it?—LEVER.

[10910].—**Prices.**—Will some experienced London surveyor kindly tell me what is the proper interpretation of the following sentence:—"The price of brickwork to include all ordinary rough cuttings and rough arches." Would it be right to read a rough arch to mean any arch that could be turned without a centre, or would it be correct to make it include any arch that could be turned in common bricks to be plastered over, provided that the centring be measured in the usual way?—RUSTICUS.

[10911].—**Light.**—I am about to build new premises upon my back-yard. Am I safe if I give my next neighbour an angle of 45° for light to his existing window? Can you refer me to a case where an angle of 45° has been ruled as of sufficient allowance for light and air?—J. W.

[10912].—**By-laws.**—Now that the municipal authorities in a number of towns are adopting the Local Government by-laws, and requiring in some instances different and advanced methods of carrying out work to what may have hitherto been in use, I, along with other of your readers, would be glad to know if there are any special textbooks published which give the required instruction and information in a simple and condensed form, showing more especially the sanitary arrangements required. I think a series of articles on these matters would be of great service to the building trade at the present time.—MODEL BY-LAWS.

REPLIES.

[10893].—**Timber and its Position.**—Before letting this discussion drop I should like to sincerely thank your correspondent "E. S." for the valuable light he has thrown on this subject. I cannot, however, reconcile myself to the fact that sap valves are non-existent, but unfortunately cannot prove that they are. On p. 380 of Rivington's "Building Construction," Vol. III., sap valves are mentioned as being present and opening upwards.—SIDNEY F. HARRIS.

[10896].—**Breaking Weight.**—With all deference to "Deputy B. E." who has appointed himself arbiter on this question, I would suggest that where authorities differ there is no "correct one" except in the opinion of each individual judge. Professor Fidler says "the strength of columns cannot be defined by any hard and fast line, even when the modulus for the whole column and the ultimate strength of the material are accurately known; but, on the contrary, the strength may have any value less than that of the ideal column within certain limits. The strength of the columns must, therefore, be represented by an area, within which the results of individual experiments may be expected to place themselves haphazard." Apropos of this question of doctors differing, "Rivington," Part IV., works out the safe resistance strength of a wooden strut 10 ft. long and 4 in. by 3 in. cross-section by three different formulae—those of Gordon, Rouleaux, and Ritter, and gets these three different results: 5·8 cwt., 15 cwt., and 29·8 cwt.! "Deputy B. E." is mistaken in thinking that I have omitted to notice that the column is "short." The formula which I gave is continuous for all proportions of length to shortest side, and assumes flat-ended firmly fixed columns. The old notion of "short" and "long" columns was a rough and unscientific method of approximating to the point at which bending

strain ceased (and compression pure and simple began. From the nature of the case it is evident that there can be no precise point at which bending strain ceases. If the shape and material of a column, as well as the precise direction of the strain on it could be perfectly adjusted ideally, there would be no bending strain in the longest column at all; but as imperfections do exist, both in workmanship, homogeneity of material, and incidence of stress, it is impossible to fix any precise ratio of length to diameter at which these imperfections may be considered negligible. I cannot express this better than is done in "Rivington IV.," which I consider the most commonsense analysis of practical rules on strengths of materials which has appeared for a long time:—"It is often the practice to divide compression bars into two classes—viz., short compression bars and long compression bars. Short compression bars are those which fail by direct crushing, and their strengths are calculated as if the pressure were uniformly distributed over the cross section. Long compression bars are those which fail by bending, so that some of the fibres are torn. A sudden change in the manner of failing has therefore been assumed. Such an assumption is contrary to all experience and common sense, and it is evident that these two causes of failure lie at the extreme ends of a series, and that between them failure arises from a gradually varying combination of the two causes." Without any intention to muddle "Student," I would remind him that it is of the first importance to know if one's formulae are the only or universally accepted ones, or whether there are many recognised formulae reaching to different results. If he has time to go into the subject, he should compare several formulae, and see how each is built up and justified. If he is preparing for an exam., he should select one and stick to it for exam. purposes; but remember that there are many more, each sworn by, by some one.—SIEN SENG.

[10902].—**Measuring Walls.**—The usual practice in measuring brickwork is to reduce the thickness of wall to the standard of one brick, or one-and-a-half bricks, according to the local custom.—R. J. ANGEL, Birkenhead.

[10903].—**Washable Distemper.**—has soluble silica for its basis. There are various kinds in the market, and it would be cheaper to buy than to make.—R. J. ANGEL, Birkenhead.

[10905].—**Valuer's License.**—The Stamp Act exempts "appraisements or valuations made for, and for the information of, one party only, and not in any manner obligatory as between parties either by agreement or operation of law," and therefore a valuer need not take out a license for an appraisal under these exemptions, but where his valuation becomes binding between parties, the valuer must be licensed.—R. J. ANGEL, Birkenhead.

CHIPS.

The sale of the old wall of Millbank Prison will take place on Tuesday next. One of the special clauses of the sale is that all bidders must agree to pay to any workman demolishing any part of the brickwork they buy a wage of not less than 6½d. per hour. This, it is understood, is the regulation price of brick-wall breakers.

During the past quarter of a century All Saints', or the parish church at Wakefield, now the cathedral church of the diocese, has been considerably altered. The work of restoration has not yet been completed, for workmen have just commenced to enlarge the organ and to rearrange the chimneys. Formerly seven tunes were performed on the bells, but in future there will be double that number. This work is being carried out by Messrs. Gillot and Johnson, of Croydon. The organ is to be overhauled and modernised, and several new stops are to be introduced; this contract has been entrusted to Messrs. Hill and Co., London.

The conversion of works of water supply for Hutton-le-Hole has just been completed for the Kirby Moorside rural sanitary authority. Mr. Robert Richardson, of Malton, was the engineer.

It is proposed to spend £4,000 to complete the structure of St. Nicholas's Church, Blundellsands, Liverpool, the erection of which a few years ago, cost £7,000.

The formal opening of the Athenæum, in Buchanan-street, Glasgow, after extension, at a cost of £30,000, was celebrated by a dinner held on Friday evening. The new wing covers the site of the Religious Instruction Rooms, and has an area of 86 ft. by 45 ft. Messrs. Burnet, Son, and Campbell, of Glasgow, were the architects, and Messrs. Dansken and Purdie the contractors.

A new line of railway between Olney (Midland) and Towcester, an extension of the East and West Junction Railway, was opened for passenger traffic on the 1st inst. The line, which is twelve miles in extent, is the last link connecting the eastern trunk line of the Midland system with the Midland in the west. The new line is single, and passes two stations—Salcey Forest and Stoke Bruerne.

The consecration of a new synagogue in Dublin was solemnised on Sunday afternoon by the Very Rev. Dr. Adler, Chief Rabbi. The building has been erected in Adelaide road, at the end adjoining Fitzwilliam-place. It has cost about £8,000.

Mr. Fred Brown, head master of the Westminster School of Art, in Tufton-street, has been appointed Slade Professor of Fine Art at University College, London, in succession to Professor Legros.

Legal.

FITNESS OF ARBITRATOR.

IN the ordinary way an arbitrator is presumed to be an independent person, and one who will approach the settlement of a dispute submitted to him with an "open mind, and entirely free from any bias or prepossession, one way or the other. This is the theory upon which mercantile and similar arbitrations proceed. But in the working out of the arbitration clauses in building contracts no such theory is presumed, and no such practice is possible. The architect or the engineer engaged by the building owner or other employer, is made the sole judge as between that owner or employer and the contracting builder. It is thus practically impossible for the arbitrator to come to the decision of a dispute in which he is himself really a party, with the independent impartiality of a judge; nor is this expected of him. Reliance is placed upon his professional position and personal honour, and these safeguards against injustice are found quite sufficient. At all events, it is now the recognised custom to make the employer's architect or engineer the sole arbitrator in any dispute arising out of the contract, and as builders are found willing to sign these contracts and accept this curious tribunal as final, it is obvious that the plan, anomalous as it at first sight appears, works out in a satisfactory manner to men of business.

The view taken of this question by the Law Courts has just been explained by the Court of Appeal in the important case of "Jackson v. The Barry Railway Company" (*Times*, Nov. 25). There the plaintiff had entered into a contract with the company for the building of a certain dock, and there was the usual clause that the decision of the chief engineer upon any dispute arising thereunder should be binding upon both parties. A question arose as to the use of stone in a part of the work, the plaintiff contending that it was not within the contract, and so should be paid for as an extra; the company's engineer, on the other hand, maintaining that it was according to the specification, and so included. The company, of course, referred the matter to their engineer under the contract for arbitration. But the plaintiff, relying mainly upon a letter from the engineer, in which he had repeated an opinion that stone must be used, went to Mr. Justice Kekewich, and obtained an injunction against the continuance of the arbitration on the ground that the engineer could not approach the dispute with an "open mind" and without bias. Upon appeal, however, Lords Justices Lindley and Bowen (Lord Justice A. L. Smith differing) have now dissolved this injunction. They did so partly on the ground that they did not consider the arbitrator's letter had prejudged the case; but much more upon the general principle that, from the very nature of the contract to refer to the arbitration of the engineer of the employers, it was impossible that he should not be to some extent biased in favour of the view he had himself urged. They held, in short, that the contractor had agreed to accept his arbitration, and in the absence of some clear proof of unfitness he was bound thereby.

FRED. WETHERFIELD, Solicitor.

1, Gresham Buildings, Guildhall, E.C.

NOTE.—All questions for reply in this column must be headed "BUILDING NEWS," and must reach my offices, as above, by *Tuesday* morning to insure answer same week.

LEGAL INTELLIGENCE.

CURIOUS ACTION BETWEEN A THEATRE LESSEE AND A CLERGYMAN.—The Rev. J. G. Haworth, of Crumpsall, was the defendant in an action tried at the Manchester Assizes on Wednesday and Thursday week—the plaintiff, Mr. J. P. Hardacre, seeking to recover damages by reason of alleged breach of contract in regard to building a theatre in the place of the old Queen's Theatre, Manchester, destroyed by fire in August, 1890, and of the lease of which Mr. Haworth was the assignee. The property in question (the rental of which was £1,300 a year) came to Mr. Haworth in consequence of the death of a relative a short time before the fire occurred. On behalf of Mr. Hardacre, the lessee, it was stated that Mr. Lawrence Booth, of Manchester, architect, acting for the owner, promised to build a new theatre in place of the one which had been burned down, in accordance with certain plans which he had prepared and which Mr. Hardacre

agreed to. After the plans had been prepared, and after the promise to Mr. Hardacre, the city surveyor insisted that certain changes should be made in them. These alterations had the effect of diminishing the seating accommodation of the theatre, and, therefore, the nightly takings. Mr. Hardacre said he was not consulted about the alterations, and never acquiesced in them. He claimed damages in respect of this and also on account of the delay which had taken place in putting him into possession of the theatre. The defence was that no contract was made for completing the theatre by a given time, and that, though the alterations—which the architect was bound to make in obedience to the corporation by-laws—were explained to Mr. Hardacre, he did not object to the work proceeding under the new condition of things. Mr. Booth gave evidence for the defendant, stating that he had never said anything that could be tortured into an undertaking to complete the building by a certain time. In the result a settlement was arrived at on the suggestion of the judge, the plaintiff being awarded £250 damages, with costs.

RE F. E. B. BEAUMONT.—In this case the debtor, a retired colonel of the Royal Engineers, states that from 1886 to 1890 he was engaged in India in the construction of tunnels for the Mysore Gold Company and the Bombay Waterworks; and that he attributes his insolvency to loss incurred in 1888-9 as sub-contractor in connection with the tunnels for the Bombay Waterworks. The liabilities amount to £3,859, of which £2,359 are expected to rank, and there are no available assets.

THE RIGHTS OF MINERAL OWNERS.—In the Court of Appeal, on Monday and Tuesday, Lords Justices Lindley, Bowen, and A. L. Smith heard the appeal case "The Ruabon Brick and Terracotta Company v. the Great Western Railway Company," in which the question involved was the right of the owners of minerals lying under a railway-line to come upon the line for the purpose of working the minerals. The plaintiffs, the Ruabon Brick and Terracotta Company, are the owners of a bed of clay, valued by witnesses at £100,000, adjacent to and beneath a branch line at Bryn-yr-Owen, near Ruabon, belonging to the defendants, the Great Western Railway Company. Two years ago they sold the Great Western the surface of a portion of the land, and the branch line now passes over it. Last January the plaintiff company served upon the defendant company a statutory notice of their intention to work the clay beneath the railway, and in the autumn they took steps to do so. As these works threatened the existence of the railway, the defendants endeavoured to stop proceedings. Thereupon the plaintiffs commenced an action in the Chancery Division, and moved for an injunction to restrain the defendants from interfering with them in getting the clay from under the railway. The motion was heard, by consent, as the trial of the action last month by Mr. Justice Kekewich, who decided in favour of the plaintiffs. In giving judgment on Tuesday, the Court of Appeal confirmed this decision, and affirmed that the owners of the minerals were entitled to enter upon the company's land for the purpose of working them.

PAY IN LIEU OF NOTICE.—On Monday a labourer named Baker sued Mr. B. E. Nightingale, the builder, for one hour's pay in lieu of notice. Baker, in stating his case, did not assert that notice had not been given him; but admitted that as soon as he received it he ceased work, with a view, he said, of clearing up his tools, and, although requested by the foreman, refused to resume work, claiming his right to do so under rule 5 of the new working rules for the building trades of London. The Lord Mayor, without calling any further evidence, said such an interpretation of the rule was preposterous, and at once dismissed the case.

The town council of Heywood, Lancs., have decided to build a technical school at a cost of about £7,000. Accommodation is to be provided for 800 students.

The new Isle of Man Poor Asylum, erected outside Douglas above Kirk Braddan, at a cost of over £12,000, was formally opened on Friday for the reception of inmates. The institution has been erected upon plans approved by the English Local Government Board, and will accommodate 150 persons.

Colonel W. M. Ducat, R.E., held an enquiry at the Guildhall, Shrewsbury, on Tuesday, respecting the application of the town council to the Local Government Board for power to borrow £7,000 for the erection of the new police-station. The town clerk stated that there had been frequent complaints in regard to the want of accommodation at the present police-office, and the town council had purchased a site on Swan Hill for £2,500. The plans of Mr. J. Johnson, of Queen Victoria-street, London, had been accepted and approved by the Home Office, and Mr. H. Price, a local builder, had entered into a contract to do the building work for £3,484. There was no opposition.

STAINED GLASS.

OSSETT.—Four stained-glass windows have been placed in the Congregational Church at Ossett, to the memory of the late Miss Pickard. They illustrate some of the more notable events in the ministry of Christ on earth and of His disciples. Messrs. Powell Brothers, of 30, Park-square, Leeds, are the artists.

ELLAND.—The large window facing the rostrum in the new Wesleyan chapel at Elland has just been filled with stained glass, to illustrate that portion of the 5th chapter of St. Mark's Gospel where the Saviour, speaking to the woman who had touched his garment, says, "Daughter, thy faith hath made thee whole; go in peace." The window is by Messrs. Powell Brothers, of 30, Park-square, Leeds.

WATER SUPPLY AND SANITARY MATTERS.

NORTHALLERTON, YORKSHIRE.—The Northallerton Local Board of Health have adopted a scheme of main sewerage for the drainage of part of the town and the County Prison, per plans prepared by Mr. D. Balfour, M.Inst.C.E., F.G.S., Newcastle-on-Tyne.

SEVENOAKS.—The Sevenoaks Local Board having applied to the Local Government Board for sanction to borrow £1,500 for sewerage extension, street works, and laying out of recreation ground, Mr. Arnold Taylor, C.E., held an inquiry at the Local Board Offices last week. Mr. Jabez Mann, C.E., surveyor to the board, produced and explained the plans for the several works, the total cost of which is £1,800, of which £300 is paid by owners of property abutting on the line of sewer. There was no opposition to the application.

CHIPS.

At Belfast on Tuesday, while two men, named Reo and Campbell, employed on new buildings in course of construction as an addition to Messrs. Ewart's mills, were engaged on the roof of a rope gable way, and they fell to the ground, a distance of nearly 70ft., and were both killed.

On the 2nd inst. Mr. D. Robinson, chief foreman of works, was presented by the officials, workmen, and others with a 12in. level, tripod, and staff, handsome writing desk, set of carvers, and a tea service for Mrs. Robinson, upon his leaving West Hartlepool to take up the duties of district surveyor to the County Council of Derbyshire. The presentation was made by the borough engineer, Mr. J. W. Brown, A.M.I.C.E., who congratulated Mr. Robinson on his success in obtaining his new appointment; he stated that the West Hartlepool Council were so satisfied with the conduct and abilities of Mr. Robinson, that they had offered to increase his salary 50 per cent, if he would remain with them. Mr. Robinson, however, while appreciating very highly the compliment paid him, declined the offer.

The town council of Arbroath have resolved to obtain the joint opinion of the Lord Advocate and Sir Charles Pearson as to their liabilities with reference to the rebuilding of the Old Church of the burgh, which was destroyed by fire on Nov. 14th.

An inquest was held on Wednesday on a railway policeman who fell down stairs and broke his neck. He resided in Newling-street, Bethnal-green, and his widow told the coroner that the stairs were very steep and had no handrail. The house was recently erected under the supervision of the London County Council. The landlord of the house, in giving evidence, said the "surveyor to the Council" had duly passed the plans. The jury requested the coroner to require the Council to inspect the building and have handrails provided.

The clerk to the Lambeth Vestry attended at the Southwark Police-court on Wednesday to support a summons taken out against the clerk of the School Board for London, charging him with failing to comply with an order to place the Johanna-street Board School in a sanitary condition. Evidence having been adduced in support of the charge, the magistrate adjourned the case for seven days, with a view to the school being closed.

At the last meeting of the London School Board, the Rev. J. Coxhead moved that the works committee should be requested to report whether it would be possible for the board to build a school without the intervention of a contractor. The proposal was negatived by thirty-five votes to nine.

At the adjourned inquest on the body of Janet Vincent, wife of an architect, held at Crewe on the 1st inst., further evidence was given as to the habits of the deceased, and the jury returned a verdict that "The deceased died from congestion of the lungs, accelerated by drinking and exposure to the cold." The Coroner strongly censured the conduct of the husband, and said he was morally, if not legally, guilty of manslaughter.

Our Office Table.

At the Museum of Ghizeh the Khedive has inaugurated the 46 new galleries which during the past six months have been added to the 45 previously existing. The collection of Egyptian antiquities commenced 40 years ago is now for the first time exhibited to the public in its entirety after years of seclusion in the museum store-rooms. Many of the older galleries have been rearranged and enriched from recent discoveries. For the first time a complete catalogue is being prepared by M. P. Virey, a French savant, and will be published in January. The intention is that the museum shall form a complete series of monuments extending from the earliest dynasties to the Byzantine period and that of the Mohammedan Conquest, when the story is taken up and continued in the Museum of Arabic Art at Cairo. The project of removing the entire collection to a fireproof building to be specially constructed for it in Cairo is under discussion.

THE London County Council decided on Tuesday to ask the Government to procure a return of the owners of land in fee in the Metropolis, the quantity held by each, and the amount received therefrom. The Local Government Board is to be asked to exercise the authority it possesses for amending the powers and improving the machinery of the Council. Further legislation is to be sought in respect to the City Guilds, the formation of district councils, the creation of a dock and harbour trust, and other matters. The Council also decided to ask the Government to provide for a new and immediate valuation of the Metropolis, in which the value of land will be stated separately from the buildings, and to seek powers in another of their Bills for the appointment of a special tribunal to hear appeals under the Valuation (Metropolis) Act. At the same meeting, the Improvements Committee reported that the improvements they had in hand were the reconstruction of four bridges in the Isle of Dogs, the widening of St. George's-place, Knightsbridge, the widening of Fortress-road, Kentish Town, and the widening of Sandy's-row, Whitechapel. They were using every effort to have the works begun at the earliest moment possible.

The special committee of the London County Council to whom, in May last, were referred various resolutions and proposals in respect to the rate of wages, have prepared a report embodying a series of standing orders and form of contract which, in the opinion of the committee, will be the best way to insure in all work done on behalf of the Council the payment of trade-union rates of wages and the observance of the hours of labour and conditions recognised by the trade-unions in the place where the work is executed. The report and recommendations are to be considered by the Council on Tuesday next.

The proposed high-level street bridge over the Thames between Ratcliff and Rotherhithe designed by Max Am Ende, M.Inst.C.E., is recommended as being cheaper than the steam ferry proposed by the London County Council and as accommodating a large amount of traffic. The span is 732ft. with concrete platform 42ft. wide. The truss is three-hinged, and a height of 90ft. is shown above high water, though it is possible to increase it to 120ft. At each end there is an inclined platform 100ft. long capable of carrying four or five vehicles. In operation a platform should start from each end of the bridge every two or three minutes with stairways on either side to allow of foot-passenger traffic. The two main trusses are of the braced bowstring type pitched at an angle of about 25°, and meeting at an apex in the centre, which is pivoted. Suspension rods carry the platform about midway between high-water level, and the apex is approached by inclined platforms at both ends.

The Birmingham Corporation received on Tuesday a report as to the total cost of the Victoria Assize Courts, built by Mr. John Bowen in 1887-91 from the designs of Messrs. Aston Webb and Ingress Bell. The total expenditure has been £113,354, whereas the estimated and sanctioned outlay at the outset, before competitive plans were invited, was £91,103. The difference was greatly reduced by the fact that in the original scheme no provision was made for the premiums for competitive designs, consulting architect's fee and sketch plans (which cost

£1,150), nor for architects' commission (£5,275 7s. 5d.), quantity surveyor (£3,511 3s. 7d.), clerk of works (£1,333 6s. 7d.), nor for expenses of laying foundation stone, road-forming, flagging, advertising, and fire-extinguishing appliances. These items amounted in all to nearly £13,400, leaving the net excess of outlay over the original estimate for building, fitting, and furnishing the courts at £8,841 7s. 6d. The report was adopted, the general feeling in the city, as elsewhere, being that Birmingham has obtained good value for the expenditure on its courts.

At the Hall of the Carpenters' Company, London-wall, on Friday night, Professor T. Roger Smith, F.R.I.B.A., delivered the fifth lecture of a free course given by the Carpenters' Company in conjunction with the Sanitary Institute. They have been on matters connected with sanitary building, and intended for candidates preparing for the examination, which takes place to-day (Friday) and to-morrow. The subject last night was "Acts, By-laws, and Official Regulations." Professor Roger Smith, having discussed the Public Health Act, passed on to speak of the law as it related to London, and then as it related to the country. These two points were enlarged upon in an interesting manner. The last lecture of this course was delivered on Wednesday evening by Mr. Henry Law, C.E., on "The Principles of Calculating Areas."

MR. C. R. ASHBEA continued, on Tuesday night, the series of lectures which he has been delivering at the Gem-street School, Birmingham, dealing with the history of English handicraft, and under the auspices of the Oxford University Extension Movement. The lecture was upon furniture and woodwork, and was in continuation of a previous address which dealt with the influence of architecture on the minor arts. Furniture, Mr. Ashbee said, was a craft dependent on architecture. Furniture had been termed the art of the hearth, because it ministered to the internal comfort of the home. There were four periods of furniture—first the Gothic, second the Elizabethan or Jacobean, third the Queen Anne (or 18th Century), and fourth the Modern period. He explained the characteristics of the four periods, saying that that of the first was very dignified, and dealt with solid oak tables, seats, church furniture, &c., and was always a part of architecture. The second was still solid and still a part of architecture, but was less serious, and was not so dignified. They saw it in country halls, panelled ball-rooms, and the elaborate joinery of old mansions. The third period was less dependent on architecture, and there was grace and slenderness in a great deal of the cabinet-work produced. The fourth period, the Modern in furniture, was no style at all, and was not dependent on architecture. The four representatives of these periods were: (1) The Gothic carpenter; (2) the Jacobean joiner; (3) the 18th-century cabinet-maker; and (4) the 19th-century machine. The lecture was illustrated with the aid of the limelight, a fine collection of wood-work and furniture of various kinds being shown by means of slides upon a screen.

MR. HARRY HEMS's art studios at Exeter were on *fête* on Saturday evening, when over three score members of his staff, together with outside friends, celebrated the 26th anniversary of his first arrival in Exeter, and of picking up the horse-shoe so closely identified with his successful career. One of the wood-working shops had been cleared, and was gaily decorated. After a capital repast, punch-bowls, pipes, and cigars were brought on. Music was given by Mrs. George Packham (the host's eldest daughter), Miss Hems, and Miss Florence Jennings, and Miss Mabel M. Hems, the latter playing violin solos. Mr. Harry Hems occupied the chair. The vice-chair was taken for the twenty-fourth time by Mr. F. Dyer, the senior craftsman of the establishment. The toast of "The Church," proposed by Mr. John Algar, the rector of St. Sidwell's, was acknowledged by the Rev. S. W. E. Bird, M.A. Alderman Domville, J.P., in responding for "Prosperity to the City of Exeter," said it was to those present that Exeter owed its present position. The toast of the evening, "Mr. Harry Hems and his Family," was proposed by the vice-chairman, who referred to the serious illness of Mr. Greville C. Hems, and expressed the hope that he might soon be restored to health. The toast was drunk with musical honours. In returning thanks, Mr. Hems said he was glad to say that their prospects for the coming year were brighter than ever.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Society of Arts. Cantor Lecture No. IV., "Generation of Light from Coal-Gas," by Prof. Vivian Lewes. 8 p.m.
TUESDAY.—Society of Architects. "Some First Principles of Architectural Design," by R. Owen Allison, St. James's Hall, Piccadilly, W. 8 p.m.
Institution of Civil Engineers. Discussion on "The Manufacture of Small Arms." 8 p.m.
WEDNESDAY.—Society of Engineers. Annual Dinner at Holborn Restaurant. 8.15 p.m.
St. Paul's Ecclesiastical Society. Exhibition of Objects of Ecclesiastical Interest, St. Paul's Chapter-house. 7.30 p.m.
Society of Arts. "The Utilisation of Niagara," by Prof. George Forbes, F.R.S. 8 p.m.
FRIDAY.—Architectural Association. "The Formal Garden," by F. Inigo Thomas. 7.30 p.m.

The Architectural Association.—December 16th. Fourth Ordinary General Meeting at 7.30 p.m. Paper by F. Inigo Thomas, Esq., on "The Formal Garden."

Trade News.

WAGES MOVEMENTS.

WAGES IN THE EXTENDED LONDON DISTRICT.—At the Bricklayers' Hall, Southwark Bridge-road, on Friday night, a meeting of building trades delegates was held to consider the present situation with regard to the strikes now in progress. The chair was taken by Mr. W. Barnes (President of the Building Trades Federation). The first question considered was the strike at Croydon, and after a long discussion, upon the motion of Mr. J. Rogers (Amalgamated Society of House Painters and Decorators), seconded by Mr. Gould (General Union of Carpenters), it was decided to support all *bonâ fide* Croydon workmen interested in the struggle, and who are willing to forthwith join their respective unions. It was also decided to vote a substantial weekly sum to the men on strike. The conference then considered the question of the strike at the Middlesex County Lunatic Asylum, Upper Tooting, and it was decided to pay the bricklayers brought out on strike the usual rate of strike pay.

DORCHESTER.—The strike at the Dorset County Asylums has ended, the contractors, Messrs. Pethick, of Plymouth, having made concessions to the men.

DUNDEE.—A meeting was held on Saturday of the Council for Forfarshire, Fifeshire, and Perthshire of the national movement for the registration of plumbers, to consider the dispute which occurred recently at the Technical Institute, Dundee, and which ended in the practical plumbers' class, consisting of 46 students, striking work, on the ground that three tinsmiths were being instructed in the actual work of their trade. The Institute Committee, on being appealed to, stated that under the terms of Sir David Baxter's trust, they were bound to admit to the practical as well as the technical class any person desiring to attend. Councillor Davidson, Perth, presided at the meeting on Saturday, and the secretary read a letter from Mr. Coles, secretary to the Worshipful Company of Plumbers, London, who inclosed a letter from Principal Garnett, Durham College of Science, where a system of instruction for plumbers has been in operation for some considerable time. Dr. Garnett said he did not agree with the Dundee Institute Committee in holding that they were obliged to admit amateurs to the practical classes. Although their college professed to receive into its classes all students over 15 years of age who paid the fees, if any, and who were qualified to profit by the instruction provided, he would refuse ironmongers, tinsmiths, and other amateurs admission to the practical classes, on the grounds that they were incapable of profiting by the classes as conducted. The teaching was intended to supplement the training of the plumber's shop, and he held that it was detrimental to other members of the classes for amateurs to attend, taking up, as they must, far more than their share of the teacher's time. After discussion, it was agreed to recommend the plumbers to return to the classes, and that meantime an effort be made to arrange matters with the institute committee.

WEST BROMWICH.—The bricklayers' labourers have gone out on strike against a proposed reduction in wages of $\frac{1}{4}$ d. per hour, notice of which was given by the West Bromwich Master Builders' Association. The wages were 5d. till July last, when an advance of $\frac{1}{4}$ d. per hour was conceded.

New stalls, designed by Mr. A. Barnes, F.R.I.B.A., have just been placed in the chancel of St. John's Church, Badminton, Bristol. They are of pitch pine, and have been carved by Mr. George Houghton, of the Society of Bristol Sculptors.

VICARIOUS DESIGN.

ONE of the strongest objections to our modern architectural system is that of its vicariousness—the delegation of the architect's duties to others. The champions of high art are never tired of recalling those periods of history when sculpture, painting, and architecture were branches of one universal art—when every workman was an artist, and every architect a master craftsman. They bid us look at Donatello, Brunelleschi, and Ghiberti of the early Medici epoch, and to the great English builder, William of Wykeham, to the crafts of metal-work and pottery, cabinet-making, and glass-painting—forgetting that the conditions of art-culture are entirely changed; that art is now “degraded” to the rank of a profession, and craftsmanship to that of a trade. We will not, however, discuss a condition of things we cannot help, if we in some degree must deplore; but we may descend to the more practical region of architectural practice as it is to-day. There are many ways in which architecture is now whittled down. We can understand the transmission of authority from one person to another; but it is not so easy to comprehend how the artist's intention can be handed down unimpaired through contractor, foreman, and workman. The impulsive stroke of the architect's own hand dictated by his mind does not admit of the same translation as that of a verbal instruction or message. When he draws with his own hand the full-size profile of moulding on stone or wood, we get pretty near to the directness of the sculptor's chisel or the painter's brush. The artist's ideal is actually brought to the material by this means; but the case is very different in practice. The eighth of an inch scale drawing is interpreted by the foreman or clerk of works; he enlarges it to a full-size drawing, and this is again handed to the mason or joiner who executes the work. The original is nearly lost in the translation; the moulding is quite another profile to that which the architect drew, or it is so distorted by bad drawing in the curves and members, that he feels disgusted with it when he sees it. How often this occurs every architect knows who cares to see his details properly carried out. Think of the repugnance of the architect who finds his Gothic moulding turned into a commonplace Classic cornice; or his surprise to find one of his choicest mouldings of a capital reversed. We have even known of such a provoking mistake as that of an octagon-shaped turret executed square on plan, owing to the neglect of making a detail in time. The misinterpretation of an architect's design is attributable largely to smallness of scale. Angles and mitres and mouldings cannot be seen, and if the architect's assistant or clerk of works undertakes the enlargement, there is a considerable risk of the design being mutilated or spoiled, unless he is well versed in the style and individual character of his master's work. The very operation of drawing a small detail to a large scale is, as every draughtsman knows, fraught with danger. Two or three inches more or less may make all the difference in a detail like a cornice or moulding, yet such a fraction can scarcely be discernible in an eighth-scale drawing, where the thickness of a line may sometimes mean a distinct member. Then the spirit of the original design or sketch is lost, especially when some mechanical method is resorted

to in the enlargement. We have frequently seen the curvature of a Gothic arch irredeemably ruined in execution because the foreman had struck the curves from too distant centres with longer radii than intended. And how often the clerk of works or carpenter spoils a four-centred or Tudor arch by adopting a scheme of centring in which the long radii arcs are made too straight, and the lower and upper arcs very awkwardly unite. These and similar mistakes arise from adopting a method of setting-out which, if the architect had seen in time, he would not have passed. They teach, no doubt, the absolute importance of showing lines of radius and centres in designs of arches, especially the necessity of the architect making the larger details himself, or at least of supervising the full-size drawings. The loss of artistic feeling in the design is particularly evident in the re-drawing by means of instruments of the architect's sketch details. First, in the process of transmitting delicate curves and touches, the artist's work disappears or is exaggerated; in moulded work the loss is particularly felt. Hand-drawn curves are spoilt by being struck in or patched up with arcs of circles, and the fine susceptibilities of the architect's taste are thus travestied. Who would conscientiously intrust to a foreman, or even clerk of works, the details of the pinnacles, or groups of pinnacles, round a spire? A small elevational drawing of such a feature could not be safely left in the hands of men who, however good as constructors, would resort to mechanical methods of enlargement. As for sculptured ornament or carving, it would be out of all question; and yet in architectural details quite as important these methods are thought sufficient to insure correctness. One word as to sketchiness. This has a fascinating charm to many architects, and in the small-scale elevation nothing tells so much in giving a kind of fictitious richness to the design; but it is indefensible when the architect leaves his sketchy drawing to be translated into working lines by others. The least he can do is to redraw them to a large scale himself, as only by this means can the errors of mistranslation be avoided, and we would impress upon the reader the value of measurements. There is much less chance of misinterpretation if detail drawings are carefully figured. We know an instance where stone window dressings and entablatures were entirely spoiled by reduction in the width of stone, the builder having taken upon himself to make the depth of stone agree with a course of brickwork less.

The “quantities” is also a hindrance to the direct transmission of the architect's design which the contractor is apt to interpret to his advantage. If any misconception of the design occurs, he appeals to the quantities, which is generally in favour of curtailment. The deficiencies of the workman are another break in the chain. He has had probably little technical or art instruction. The drawings he receives from the foreman have already been interpreted for him by the terms of the contract. It is the contract ideal that is set before the worker. Impeded he is also by other considerations. He receives, probably, only a tracing of the architect's drawing, or the foreman sets out on a board the intended detail. In a mechanical and perfunctory manner the material is converted and put together. Excellent as a workman, the artificer has little knowledge of style or the art which enables him to rise above his tools; the result is necessarily disappointing. The architect is less in touch with the manufacturing artist, who is often above receiving instructions, and prefers to assert his own individuality. We have thus far been speaking of those who submit their own designs to the contractor; and how very little the architect's own skill and artistic power

are actually translated into the materials of a building! But what is to be said of individuals who habitually depute others to do the work for them? The architectural draughtsman who ekes out a living by assisting competing architects by making perspectives is by no means always the invisible personage known as a “ghost.” Though behind the scenes, he somehow makes his presence known rather awkwardly, frequently by an objectionable course of action in case the design is favourably received, much to the discomfiture of the *soi-disant* author; at other times by demanding some share in the participation of profits. But as far as the actual workman goes, the architect is truly a phantom, for neither the worker nor the material know anything of him, so that the design and the building are irreconcilable.

The practice of delegating the artistic part of the work to another is, we are sure, too largely followed by members of the profession who have obtained some skill as specialists; the result is to dissociate in a most pernicious degree design from actual construction, and therefore the practice of art from the artist. In certain branches of art craft the architect finds it easier to depute to expert designers the whole responsibility, thus handing over all those portions of his building which should have unity of conception and aim. But is not this delegation of authority contrary to the whole meaning of art? It is impossible, perhaps, now to combine the faculties of artist and executant, but it is the duty of the architect to reduce the steps and shorten the labour of translating his design upon paper into actual material.

REPAIR OR REBUILDING.

WHICHEVER we like. We do not suppose for a moment that we can stay that process of natural decay which threatens every one of our noblest buildings; but it is idle to imagine that anything short of periodical reparation can prevent their destruction. To sit by and see stone by stone decay or become dislodged by wind and frost is the idea of those who would never do anything to an old edifice that would rob it of its antiquity, but would rather that it went piecemeal to ruin than do anything to avert a catastrophe, except, perhaps, putting up a shore or two. Some people appear to think that our old buildings, because they have weathered so many centuries, are indestructible by natural forces, forgetful that more modern erections have cost thousands to keep in an efficient state of repair. It is as well to remember there is a certain limit to repair. One feature after another may disappear or decay till a time comes when repair is past, and the whole structure can only be rebuilt or restored at an enormous sum—a fact which has been painfully brought to our notice of late in the restoration of edifices designed by one of the most eminent church architects of modern times, and by the serious and threatening state of the beautiful base of the spire of St. Mary's Church, Oxford. Custodians of our ancient edifices have a great responsibility; a timely appropriation of funds to the repair of piers, towers, and buttresses would save many a disastrous accident. In too many instances we know of, repair has been put off till it is too late to do anything but reconstruct the part at a great expense. Take, for example, a central pier supporting a tower. A stone here and there is fractured or decayed: instead of being at once reinstated, they are allowed to remain. Several years later the fractured stones multiply; a subsidence of the pier has taken place in one part, probably bringing the weight upon some portion of the external ashlar till it becomes apparent that the pier must be shored, the superincumbent

weight relieved by costly needling and collars, and the fractured part of pier made good. Often this operation has led to the entire rebuilding of the pier from a new foundation, a process that has been gone through in many of our cathedral churches. Where we can prevent this by timely reinstatement of new material, it is far better than the alternative of rebuilding, which is unsatisfactory both from an archaeological and architectural point of view. What does it mean but to destroy all the old, and rebuild stone by stone a new edifice that has not a particle of claim on our sympathy? Thus the spire of St. Mary's, Oxford, might have lost all its charm as an historic work. Happily it is in good hands, and although the architect, Mr. T. G. Jackson, says it has "gone to complete ruin in all exposed parts, as the pinnacles and parapets," we shall still have a careful and sympathetic rendering of the old detail, preserving the original beauty and charm of the outline of this spire, the "glory of Oxford," with its incomparable grouping of pinnacles, so far indeed as we care to take the new for the old.

We have many modern structures that equally demand periodical vigilance. The condition of the stonework of the Houses of Parliament requires watchfulness, and though much has been done in applying solutions and in reinstating decayed parts and pinnacles, other signs of decay are apparent in the external details. In several Government buildings where stone is largely used, such as the Royal Courts of Justice, periodical attention is required, especially in those features which project like cornices and stringcourses, and ornamental details like pinnacles. Particular attention ought to be directed to stonework cramped or doweled by metal, as portions are apt to become fractured by rusting of the iron, and to become dangerous by falling.

After stone, the necessities of iron construction demand the greatest of care. Many of our iron bridges are badly protected from the weather. Oxidation of plates and flanges and bolts is constantly weakening those parts subjected to stress, and we have from time to time serious failures in consequence. Repair in these cases is perhaps more difficult than substitution of new members; but an effective course is to protect by wood or asphalt casing the main girders, and to draw off the water from the floor beams. The embedding of girders in concrete is one of those questions that engineers will have to consider in the future, if only as a protection from external agencies. Possibly also it will be found to add to the strength of the girders by increasing the resistance to compressive and tensile forces. The iron roof has to be regarded also as a structure susceptible to the corrosive action of acids and moisture. Protective coverings and paints necessarily come within the category of repairs; yet we question whether our iron structures receive the proper attention in this direction. Many iron bridges on metropolitan railways have not received a coat of paint for several years. Various protective paints are advertised, some exceptionally good, and we have the recommendation of the French Marine Department of the value of tar-smoke painting, which has been found to prevent corrosion; but the same apathy exists as in the case of stone buildings: often companies will not repair till they are compelled to reconstruct. Railway structures, which are generally supposed to be models of economical construction, are often flagrant instances of neglect. In not a few instances the platforms are roofed over by flat coverings of zinc on wooden rafters or bearers. Whenever there is a sharp frost, the sheets contract or break at the joints, or the laps are so imperfect that the rain or snow descends in copious drops over the passengers.

It seems needless to say that flat zinc roofs should always be avoided, unless the sheets are of superior quality and laid in a scientific manner.

THE SOCIETY OF ARCHITECTS.

THE third ordinary meeting of the Society of Architects was held at St. James's Hall, Piccadilly, on Tuesday evening, Mr. E. J. Hamilton, vice-president, in the chair. The following three gentlemen were elected as members:—Lawson Robert Ford, St. Thomas's Chambers, Railway-approach, London Bridge, S.E.; Nathaniel William Harrison, 51, Pembroke-street, Cowley-road, Oxford; and Herbert Edmund Knight, 129, Cheapside, E.C.

The following paper was read by Mr. R. OWEN ALLSOP, entitled

SOME FIRST PRINCIPLES OF ARCHITECTURAL DESIGN.

The lecture was illustrated with more than forty limelight views of typical buildings of various styles and countries. The author remarked that to those possessed with a spirit of inquiry into the genesis of things, it must often have occurred that certain broad principles are the first cause of all beauty of effect in architecture of whatsoever style of design. While there are principles pertaining to each individual style, there are others that equally concern all true and noble architecture. Of these former—what may be called "particular rules" as distinct from general laws—we have heard much since the days of the revivals; but little has been said concerning those great principles that lie at the very root of all true architectural effect. Principles of style are indispensable; but a knowledge of these alone will not insure beautiful design, even in the particular style to which such rules apply—that is to say, they will not insure original and intrinsic beauty. At the most they will only guarantee a correctness of resemblance to some ancient model or prototype, and the fuller the knowledge of principles of style, the closer will be this resemblance. First principles of design, on the contrary, go to the root of matters. They discover the fountain-head of architectural beauty. While the principles of style assist us only in the machine-like production of the beautiful, an earnest study of first principles will give an insight into the method of producing intrinsic beauty and that which is novel and original—so far, indeed, as anything can be called new and original. Never was there a time in the whole history of architecture when a broad study of the subject of architectural composition would be of so much benefit to the architect. So many different styles are practised at the present day that an insight into the great principles of design is as useful to the architect as the mariner's compass to the navigator, or the pole star to a traveller across the trackless desert. In a rushing, changing and bewildering age, with ever-varying tastes, it is a beacon-light indicating a sure and certain haven of refuge. He would be bold and presumptuous indeed who pretended to be able to point out a royal road to successful design either by principle or otherwise, and in one short hour to unveil the mysteries of recondite primary laws and first causes, that have taxed the expressional faculties of the most profound thinkers. All that I hope to do this evening is to draw your attention to the existence of these first principles as they affect architectural composition, and so perhaps to initiate further thought in the same direction. Much that we can feel in art and design cannot be communicated. Were it otherwise there would be no art. Much, too, cannot be directly taught: we feel by sympathy that which the writer or speaker strives to express. Thus, in reading the works of those authors who have taken a high standard in writing of architecture as an art, we glean, rather than reap, golden grains of truth. Such eternal truths—for so we may call them—are rather felt than spoken; and thus we have the highest first principle of design—one which for want of a better term we call feeling—a purely ethical matter which, possibly, has as much to do with the heart as the intellect. This vague, ill-defined principle we call feeling is a point of the greatest importance in architectural composition. It insures enthusiasm, earnestness and sympathy in design, and is as necessary an attribute of the

designer as of the craftsman who executes the work. It means a love for and an absorbing interest in one's work. Nothing really great can be accomplished without it. It is to be questioned whether there can be this enthusiasm in the mere copier of old design. Laborious imitation is always painful and tedious, and it is only when ideas fresh and novel—or apparently so—well up, so to speak, at the fountain-head, that true joy in design is experienced. We may therefore lay it down as a great first principle that no noble design is the work of an unsympathetic hand or hard heart, howsoever keen the intellect. Enthusiasm for the cause of the building is evidenced in all great architectural creations. It is the first of which we are sensible in contemplating any great work of architecture. It leads to the expression therein of a spirit of life. "All things are noble in proportion to their fulness of life," it has been said. In every great building there is a vigour of both design and execution that symbolises power and force, and may be perhaps regarded as crystallised energy. We rarely find this expression of living energy in any works produced on the principle of slavishly copying old examples. What is vigour in the original, is feebleness in the copy. Enthusiasm and the life and vigour that are its resulting expression, are rather matters of architectural ethics, and the result of moral forces, than laws of that grammar of which architectural composition is the practical exponent. To pass on to more matter-of-fact principles, we find that there are great laws of contrast and gradation—principles that not only underlie all artistic work, whether in music, literature, the drama, art, or architecture, but are of the essence of all effects that have been in the heavens or the earth since light and darkness were divided. Here, then, we have first principles indeed, and such as very evidently affect architecture of every age and style. Contrast and gradation are the soul of all artistic effect, and embrace many other minor principles, such as concentration, radiation, breadth, and even proportion itself. To obtain harmonious contrasts and noble gradations is, even if unconsciously, the great effort of all designers and composers. In architecture we may have contrast of light and shade, of form, of line, and of material and colour. Let an architect rather than test his design as to its resemblance to some old model, ask himself the question, "Have I got sufficient contrast in this or that feature?" and again, "Are my studied gradations of light and shade, of form or line, &c., beautiful gradations?" "Do I want more contrast, or a bolder or more harmonious contrast here?" may be a method of self-examination applicable to outline, to the grouping of parts, to details and to mouldings. A section of a capital or archivolt does not appear satisfactory. "Are the contrasts of square to round, of large to small member, of light projection to dark recess sufficiently pronounced or too much so?" will be a question, and a far more pertinent question for the striver after new beauties of effect than a mere reference to some old example or book of examples. The one is the method of the ape-like imitator; the other that of the thinker and true designer. In the same way a design may be overhauled with reference to gradation. "Are all curved forms and lines and surfaces noble and beautiful curves; are all studies to produce effect by graduated design really noble and interesting gradations?" "Is there a false note in the scale?" Such and numerous similar questions will at once occur to all. More important almost than contrast and gradation is the law of domination and subordination—more important because affecting the massing of the great features of a work of architecture. Domination and subordination simply mean the giving to each feature its due weight and importance. To take a homely illustration, the advertising poster or trade handbill shows the printer's appreciation of the rule of domination and subordination in giving due prominence to certain words. A newspaper contents bill is another illustration. Any indispensable conjunctions, &c., are printed in comparatively insignificant type, whilst news of importance is prominently displayed. In architecture relative weight must be given to each feature. Some hold that the Belfry of Bruges is a composition defective by reason of the tower dwarfing the building. As a matter of fact, the tower with its clock and beautiful carillons being the chief end and aim of the whole building; this

would seem to be a fine example of a just appreciation of the law of domination and subordination. In every fine work of architecture there is to be noticed some dominant feature, such, for example, as the dome of St. Paul's and the Bell Harry Tower at Canterbury, both being objects marking the central portions of their respective cathedrals. A nice appreciation of this matter is requisite for attaining a good effect in designs, where the proper position of a dominant object is not so plainly evident as at the crossing of a cathedral. It is by means of due regard to this principle of domination and subordination that unity is attained in a building comprised of a multiplicity of features. Unity in multiplicity is another great first principle in design. Unity without multiplicity of parts is not difficult to attain. There is unity in the Parthenon or any old temple of such simple composition, as there is unity in the pyramid. In such simple masses there cannot but be unity; in a complicated building, covering a wide area and devoted to a variety of purposes, unity must be sought in a deliberate apportioning of size and importance to each feature; and if this be successfully done a mediæval monastery has nearly as perfect unity as a Greek temple or Egyptian pyramid. Lincoln has unity of effect, all its main features are in harmony duly related and proportioned one to the other, its great central tower dominant, its western towers in due subordination; and so more or less with every minor feature. Durham, Lichfield, and Canterbury—most of our old English cathedrals are in perfect harmony in this respect. Interiors are necessarily so—some more, some less. The interior of the church of St. Ouen at Rouen is a perfect, self-contained unit. In respect to domination and subordination and unity of effect, therefore, we have here another matter for self-inquiry on the part of the architect. "Has my design unity; is it undeniably one in effect?" "Is there a due and harmonious relation between feature and feature, or are they all more or less of similar value?" "Can I by subduing this part and giving greater prominence to that obtain a better and nobler effect?" "Is the composition, like a feeble picture, 'all over alike' as respects the grouping of features?" "Is there, in fact, insubordination or over-modesty among the members comprising the building?" Such questions, moreover, it should be observed, can be applied to the outline and main grouping of features as well as to the most minute detail. There is not a moulding or a fragment of carving in a building that this principle does not affect. In Classic or Gothic architecture the same inexorable law applies. Much of that otherwise mysterious attribute of architecture—proportion—has to do with this law of domination and subordination. To give a feature its due weight and prominence is evidently to "proportion" it. Of proportion as a principle I do not propose to speak. It would seem to be rather the resultant of the application of other principles than a principle itself. This much may be said—that to all holding that proportion must, should and can only be infinitely elastic, the hard and fast triangular and other principles of some theorists are peculiarly revolting. An important first principle is concentration. This law of design affects both detail and the larger matters of architectural composition. Concentration is the antithesis of diffusion. It signifies the throwing of one's whole energy and strength into certain parts of a design. It insures the observance of the rule of ornamenting construction—a principle of architectural design so well known that I make no special mention of it here, my sole object being to draw attention only to commonly neglected first principles, and to ignore as platitudes those well-recognised laws which compel honesty of construction, proper use of materials, suitability of design, &c., &c. Want of knowledge of the power of concentration in design leads to that neglecting of necessary features and restless creation of so-called "ornament" for its own sake—the chief characteristic of the incompetent designer. Half the battle in architecture is the concentration of work upon necessary features, leaving plain wall-surfaces to take care of themselves, which they very well can do. In the work of a tiro we see how he slurs over necessary features, as, say, a doorway, and feverishly hastens to fritter away with meaningless "ornament" all the broad surfaces of adjacent plain walling. The true architect, on the other hand, will spend much time and thought on the doorway, its arches and mouldings, and on the

door itself, with its panels and fittings, leaving the plain wall surface as a natural contrast. It is to this principle of concentration that we are indebted for the grand portals of Mediæval cathedrals, and, indeed, for every feature in a design, in whatever style of architecture, where concentrated thought and persistent endeavour are evidenced. The distribution of light and shade—architectural chiaroscuro, so to speak—lies at the root of beautiful effects in building. It is the great principle of Mr. Ruskin, who speaks of "broad sunshine and starless shade," and instances Giotto's Campanile and the Grand Canal façade of the Doge's Palace at Venice as examples of beautiful disposition of light and shade. The latter building may also be shown as a grand example both of contrast of void to solid, and a concentration of work in one particular portion of a design. A crucial test for an architectural composition with respect to this disposition of light and shade is moonlight. Full moon on a building like the Doge's Palace cannot but show the design in another beautiful aspect. And so with all other good compositions. Where, however, the main massing of features is at fault, the moon reveals the errors. Few modern works of architecture can withstand this test, as few faces are so beautifully modelled as to be proof against the searching rays of the electric arc-lamp. In moonlight the obscuration of the details—which become blurred, indefinable, and mysterious—leaves us only the outline and general composition with which to judge the work; and as the lights and shadows are hard and exaggerated—dead black and glaring white—defects in their disposition are more easily detected. To obtain a beautiful and graceful disposition of light and shade the arrangement of voids and solids of a building must be carefully studied, that no harsh shadow or glaring light breaks in discordantly upon the general scheme. To obtain a grand distribution of light and shade, deep recesses, and flat unbroken wall surfaces, as contrast, are required. An indifferent climate, thin walls, abundant plate glass, and local by-laws, are not conducive to fine effects of light and shade in architecture. An Egyptian temple under a blazing sun is required. Among notable bold effects of this kind, in internal composition, the triforium of a cathedral may be instanced, the blackness of these sombre arches contrasting so finely with the brilliant light in the clerestory windows. The interior of almost any cathedral will illustrate this. A fine effect of this kind is to be witnessed in the unglazed window openings across a cloister garth. This care in the distribution of light and shade in works of architecture has much to do with the ultimate attainment of that breadth of effect—which is so much to be desired and so seldom attained in modern buildings. "Breadth" in art matters seems capable of several slightly varying definitions. In pictures it seems to be recognised as such a distribution of light and shade as shall give the reverse of that spottiness of effect observable in drawings faulty as to chiaroscuro. In architecture the term may be applied more widely. A building with many different kinds of materials will lack breadth as compared with one where fewer and simpler materials are employed. Anything petty and frittered will negative broad effects, and especially the want of feeling for the value of plain wall surface. Variety we know to be charming; no need, therefore, to put forward variation in parts and methods as a principle: but given this fact, something would seem to require explanation, seeing that repetition of similar features and monotony in surfaces are evident attributes of all architecture. This, apparently, is to be explained by the fact that the grandest and noblest of all architectural effects of gradation is the perspective view of what on a geometrical elevation may be simple repetition. A colonnade, as of a portico, presents in perspective a glorious effect of gradation. A receding arcade is equally fine. Again, what is geometrically a plain, even superficies never, as is well known, presents anything but a varied gradation of light and shade. So, too, a diapered surface, as in the spandrels of arcade arches, monotonous enough in its geometrical representation, becomes in perspective a surface piquant with beautiful effects of graduated and broken light and shade, each diaper being presented to the eye in a different form and varied tone. Thus nature aids the crude endeavours of man, and transforms a dull, lustreless stone into a sparkling gem. In a similar way parallelism in

a geometrical elevation, which properly speaking is monotonous in effect, becomes, in perspective, divergence. This may be seen in any building, and is a notable effect in a long and lofty interior such as that of a French cathedral. Radiation or divergence is an important principle of design. It is plainly an element of the beautiful in ornament, and is to be particularly observed in vaulting, notably in such fine examples as that of the Chapter House at Westminster. We see the beauty of radiating lines throughout nature—in flowers, ferns, leaves, and grasses. An architect could frequently improve details, such as capitals and other carvings, by calling to mind this principle of radiation, and asking himself whether there is an ignoble weakness or expression of power in the radiating lines of his design. Radiation would seem to express power. Power must proceed from point or centre. In a mass of radiating lines we see expressed the spirit of the same effect as that which attends an explosion, as in the firing of a cannon, when from the muzzle of the gun rolls away an ever-widening cloud of smoke. So, too, a similar impression is conveyed by the ever-extending circles on the calm surface of a lake when we cast a stone into the water. Power, proceeding from a centre, is in all these cases typified. In reflecting on first principles the architect will discover many minor ones not mentioned this evening. I have confined myself to those of the widest significance, and if the suggestions made should lead to your prosecuting individual inquiry in the same direction, I shall feel that my endeavours have not been in vain. During recent years great progress has been made in architectural design; but something seems lacking in respect to originality of composition—in respect, perhaps, of insuring originality of composition that may be really beautiful. Too great attention to style, and too little regard for principle, would seem to be the cause not only of much insipidity of design, but also of much positive ugliness. One may continually see buildings wherein it is but too evident that little regard has been paid to any of the eternal laws of beauty in concrete substance. We are only able to conclude that there are not a few architects living and working in blissful ignorance of even the existence of such things as laws of architectural composition, and wholly unaware that there are beautiful effects peculiar to architecture—men who continue absorbed in petty matters of detail. Totally oblivious of the larger matters of outline and the dignified and beautiful massing of main features, they apparently cannot grasp the idea of a building as a whole, but habitually regard it with the narrow eye of a decorator. Any such once awakened to regard a building as a building, and not as a screen or museum for the display of petty fancies, quaint architectural conceits, and odd fragments of ornamental carving, would surely perceive that the noblest attributes of architecture must necessarily be beautiful effects peculiar to architecture as it presides in the street or square, or stands forth from the country side. Were architecture a matter solely of an exhibition of pretty windows, gables, and elegant mouldings, then we could see all the beauty of architecture in a museum. Modern architecture has made rapid strides, but it cannot be said to be noteworthy for its large and noble effects. The neglect of the study of composition—that is to say, the grouping of features and the massing of great parts until unity is attained—would seem to be the great error of the time. A taste for, and an inquiry into, first principles would go far to remedy this.

Mr. WILLIAM ALLPORT moved a vote of thanks to the lecturer.

This was seconded by Major LESLIE, R.E., and supported by Messrs. A. G. SMITH, W. H. MAY, ELLIS MARSLAND, and ALFRED HOWARD, and was carried by acclamation.

PRIZE WORK AT THE ROYAL ACADEMY.

"GRATIFYING to the authorities, creditable to the students, and full of hope for the future," were the words used by the President of the Royal Academy, Sir Frederic Leighton, the other day concerning the prize work which has been on view this week at Burlington House. "The average of the productions, taken as a whole," he said, "was excellent." A very large assemblage of members of the Academy were present, and the chairman, before distributing

the honours to the prize-winners, told the students that this view was not only his opinion, but the united judgment of his colleagues. Mutual applause followed. In the face of such an expression of opinion, however, little remains to be said—indeed, it is reckoned sufficient to silence criticism. The impression notwithstanding which we find forced upon us, after examining the show, is that the majority of the competitive works are extremely poor. Certainly the architectural productions at best can but rank as quite unworthy of a national institution professing to cultivate the art of architecture, and no more severe comment could be made on the absence of all helpful influence upon the students' work by the architect members of the Academy than the building designs exhibited on this occasion. All the recent irresponsible chatter about "Architecture as a profession or an art" seems mere sounding of brass and tinkling of the cymbal while the practical outcome of the schools of Burlington House, with their R.A. visitors, only produces such class-work as is here shown, exhibiting it, moreover, as the best of its kind done during the year. Two or three of the architectural prizes were not awarded at all, and even in the Creswick Landscape competition, for which there were several entries, the second prize was not given, so that we can hardly see where the occasion for congratulation exactly finds a place.

The following is the prize list:—Landscape painting.—A Trout Stream—Creswick prize (£30), Siegfried Makepeace Wiens. Painting of a figure from the life (open to male students only).—Silver medal, 1st, Lawrence Edward Koe. Painting of a head from the life.—Silver medal, 1st, Isaac Snowman; 2nd, Edward Spilbury Swinson. Painting of a draped figure (open to female students only).—Silver medal, 1st, Isabel C. Pyke-Nott; 2nd, Florence Hannam. Cartoon of a draped figure.—Mary Magdalen at the Sepulchre, St. John xx. 1.—Silver medal and prize (£25), Lawrence Edward Koe. This figure is probably the best; but the drawing of the hands is a great blot in the composition, which, as a whole, is wanting in intensity, and evinces a lack of appreciation of the character. The woman who was sufficiently fired by love and zeal to risk the dangers of the night and face the rough reception only to be expected from Roman soldiers eager for the safe custody of their charge, was little likely to stand crouching, helplessly bewailing, supporting herself against a rock, as is here delineated! Design in monochrome for a figure picture.—The Judgment of Solomon, 1 Kings iii. 24-27.—Armitage prizes, 1st (£30 and bronze medal), John J. Liston Shaw; 2nd (£10), Harold Edward Speed.

Design for the decoration of a portion of a public building.—Autumn—Prize (£40), Beatrice Emma Parsons. None of the designs for this prize are, correctly speaking, decorative work, which is manifestly not encouraged or properly understood at the Royal Academy. The prime restrictions of flat treatment and silhouette drawing as leading principles always seem to be ignored, and, naturally, it would be so with portrait and cabinet picture painters, such as are out and away in the majority at the R.A. Miss Parsons' work, besides being treated too naturally for mural ornament, is wanting in grouping, seeing that the figures remain individuals almost entirely, and either one could be removed without being necessarily missed. The colouring of the work, too, seems unsatisfactory, except the kneeling woman to the left, in green, engaged with the yellow-haired child.

Set of six drawings from a figure from the life (open to male students only).—1st prize (£50) and silver medal, Frederick Dudley Walenn; 2nd (£25), Herbert Edward Harley; 3rd (£15), Lawrence Edward Koe (disqualified owing to having received a superior prize in the same competition before); 4th (£10), Leonard Watts. Drawing of a head from the life.—Silver medal, 1st, Edith Lydia Clink; 2nd, Shirley Charles L. Slocombe. Drawing of a statue or group.—Silver medal, 2nd, Hannah Myers. Model of a design.—Astranax hurled down from the ramparts of Troy in the presence of his mother, Andromache—1st prize (£30), David McGill; 2nd (£10), Charles Beacon. Set of models of a figure from the life (open to male students only).—1st prize (£50) and silver medal, David McGill; 2nd (£20), Sidney Herbert Physick. Model of a bust from the life (open to female students only).—Silver medal, 1st,

Edith Bateson, the only competitor in this division. Model of a design containing figure and ornament.—Frieze for a chimney-piece.—Silver medal, Charles John Allen. Design in architecture for a small country church for a scattered moorland parish—the Travelling Studentship and £60 is awarded to James S. Stewart, who scarcely wins the prize, so closely is he followed by the design marked 182. The subject is a small one, comprising, besides the little moorland parish church, a Sunday school detached from the church, and a shelter for carriages or carts bringing worshippers from a distance. Mr. Stewart makes a feature by placing a squat conical spire over the tower-like gateway located between the school and the shelter, the church being placed in the centre of inclosed plot. This tower reminds us of some prize designs for mountain churches, published about twenty years ago by Messrs. Paley and Austin, and we hardly think the Seddingesque influence which other features in the design indicate harmonise with the sterner type of work which mountain or moorland buildings necessitate. The Flamboyant traceries and unprotected external doorways here shown are not appropriate for exposed situations. The church plan evinces no special knowledge of church planning, and the canted sanctuary in a sort of apse would be ugly enough in execution. No. 182, the second best design, has a thin, spire-capped tower, belfry and all. The school is connected with the church by a covered way, and, presuming that the site is a hilly one, a shelter is made very picturesquely at a lower level under the school-room. This design is "Late" in style, and is not very suitable for the presumed position, where half-timber work would hardly look at home. The other three designs do not call for any remark, as they clearly were not in the running. Probably if they had been prepared in some out-of-the-way country office they would have been quite as good, and this is not over-stating matters, relatively speaking.

Only one plan was sent in for the infectious hospital, and that not being equal to the standard contemplated fails to win anything. For a set of architectural drawings of the north porch of St. Paul's Cathedral a silver medal, 1st, was given to Robert Alex. Reid, and a second medal to Henry Ernest Kirby. For a set of drawings of an architectural design (Lower School), Harry Percy Adams takes a prize of £10. The Landseer scholarships in painting and sculpture of £40 a year each, tenable for two years, given for the best work done in the examination for passing into the second term of studentship, have been awarded—in painting to Reginald Arthur and George Spencer Watson, and in sculpture to Sidney Herbert Physick and Lawrence Edward Koe.

A SANITARY MUSEUM, HIGHGATE.

THE Hornsey Local Board, Highgate, have opened a Museum of Sanitary Appliances which ought to be a lesson to other local boards. To the engineer and surveyor of the Hornsey Local Board, Mr. T. de Courcy Meade, M.Inst.C.E., the inception, or at least carrying out, of this scheme is, we believe, mainly due. Last week the Lord Mayor formally opened the museum, which contains a most instructive and comprehensive collection of sanitary appliances. Manufacturers were invited by the Local Board to submit specimens, and the response has exceeded the expectations of the promoters. The museum consists of seven rooms, having a floor space of nearly 5,000sq.ft., and the rooms are well lighted and warmed. The most valuable and instructive part of the museum are the annexes in which materials are tested, the cement testing apparatus being very complete. The materials are selected and prepared with great care, briquettes are made and tested, besides stoneware pipes, bricks, water fittings, macadam, &c. In the plumbers' workshops several useful sections of plumbing arrangements and models in glass for showing the action of liquids in soil pipes, &c., are exhibited, besides several kinds of flushing tanks, which are shown in operation. Plumbing classes are being organised, and lectures will be given on sanitary science.

Glancing over the varied contents of the museum we find in Stand 6 a select and typical display of ventilating appliances presented by Messrs. Robert Boyle and Son, Limited, of Holborn Viaduct, the well known sanitary engineers. These include an air-pump ventilator

for the ridge of roof, which is now so well patronised by the profession, an external pipe ventilator suitable for soil pipe or a system of house drains, an air-pump drain and sewer ventilator, and a galvanised iron fresh-air inlet with mica flap, an inlet which every house should be provided with. A bronzed cast-iron ventilator for chimney-breast is a useful self-acting flap arrangement. Messrs. Hayward Brothers and Eckstein, Union-street, Borough, in Stand 39, have an assortment of their ventilators, as the "Silent" and "Self-acting," and inlet louver ventilators. These are intended for fixing in air-extraction flues, chimney-breasts, and outer walls, and are made with ornamental bronzed fronts. One of the best exhibits in the patented closet arrangements is presented by Messrs. John Knowles and Co., of King's-road, St. Pancras. The "Presto" double-action, self-flushing cistern and seat, adapted to the Woodville pedestal wash-out closet, is already favourably known. We described its advantages and self-cleansing action lately, and can only say that this model closet-seat and cistern has only to be examined to be approved, and is suitable to every class of dwelling, and especially to public schools and hospitals. We notice an excellent white earthenware wash-out w.c. basin and lavatory. Improved siphon traps, yard gullies, and stoneware channel-pipes with special safety joint are shown in models.

Messrs. Doulton and Co., Lambeth, are represented on several stands, and their exhibits include specimens of their white earthenware valve closets, the "Simplicitas," in decorated blue and white and other wares, with washdown basin and trap in one piece, a hinged seat fitted with water waste-preventing cistern; also the Queensware "combination closet," with self-raising seat, &c.; models of stoneware "Kenon" disconnecting trap, stoneware and gully traps. In Stand 37 several improved forms of stoneware intercepting traps, with inspection inlets and ventilating arrangements, are exhibited; besides a 9in. stoneware tested pipe in three lengths, fitted with self-adjusting joints under water test—a good example of a stoneware drain pipe. Damp-proof courses in stoneware and other goods are to be seen, including a stoneware invert block and several specimens of terracotta and blue Staffordshire bricks, silicon treads for steps, &c. Messrs. Adams and Co., Little Queen-street, Westminster, present an automatic flushing cistern of good design; the Albion Clay Company, Euston-road, the "Paragon" stoneware pipe joint; Messrs. Ashton and Green Iron Company, St. Mary Axe, sanitary wash-down closets, lavatories, Roman and other baths, showing improvements, and a variety of waste-preventing cisterns and ventilating fittings too numerous to mention; while further on we must not overlook the important stand (130) of Messrs. Thos. Crapper and Co., whose sanitary traps for disconnection, channel pipes, and gully traps are well known and appreciated. Messrs. A. Kershaw and Co., Lancaster, the London Galvanised Iron Co., Walter Macfarlane and Co., Glasgow, and J. Stiff and Sons, Lambeth, are also exhibitors.

VENTILATION.

A PAPER on the above subject was read at the Royal United Service Institution, Whitehall, on the 7th inst., by Captain George S. MacIlwaine, R.N. (Ret.), Travelling Inspector to the Board of Agriculture. In the course of his remarks the lecturer said that the subject was one of such vital importance that it was impossible to over-estimate it, and in support of this opinion quoted an authority, who states: "There is no subject of greater importance to the welfare of human beings than ventilation, or the proper supply of fresh air. Air is a necessity of life, and when it is remembered that no one can abstain from inhaling that which immediately surrounds him, whether it be pure or not, the importance of the subject becomes apparent. Bad food or bad water can be rejected, bad air must be used." Go where we will, said Captain MacIlwaine, into halls, churches, theatres, hotels, private houses, what do we find? Either that there is absolutely no provision made for ventilation, or that the arrangements made are quite inadequate to the requirements of the place or the people occupying it. It is, therefore, of the last importance that the matter be thoroughly understood, and proper provision made for what

is so essential to well being. But immediately the question arises, How much pure air must be supplied?—how many cubic feet per hour per head? It would appear to be a matter easy of decision, and yet what extraordinary differences of opinion do we find concerning it. Here is an authority, mark you, who writes and publishes on the subject, who may be presumed to have some knowledge concerning it—and who says: "A man in health requires not less than 150 or 160 cub. ft. of fresh air per hour." In the "Text-Book of Human Physiology," by Lambois J. Stirling, it is laid down that 3,000 cub. ft. per head per hour are necessary to counteract the effects of the CO₂ manufactured by the breath. We have here some startling differences of opinion. If 150 cub. ft. are enough, it is clear 3,000 ft. are too many, and *vice versa*. About 15 cub. ft. of air pass through an average man's lungs in an hour; the expired air contains about 4.4 per cent. of CO₂, or carbonic acid, as it is popularly called—i.e., a man manufactures about 0.66 cub. ft. of CO₂ every hour. Ordinary air contains 0.04 per cent. of CO₂, or four parts in 10,000. For health the air we breathe must not contain more than 0.06 per cent. of CO₂, or six parts in 10,000. Dr. C. Hunter Stewart, of Edinburgh, has recently made some experiments in the matter of the analysis of the air in different places in Edinburgh. He mentions one place where 63 parts of carbonic acid in 10,000 were found—that is, more than ten times what ought to have been. In other churches he found from 20 to 50 parts in 10,000. Knowing approximately the amount of air required, the next question is, How can it be provided? And here again we find the widest divergence of opinion among the experts. For instance, Mr. Tobin, the inventor of Tobin's pipes, says: "It is unnecessary to arrange for outlets for foul air, all that is necessary is to admit a sufficient amount of pure air." Dr. Macdonald says: "The more we study the subject, the more we perceive it to be necessary to make provision for the ingress of fresh air, as well as for the escape of that which has been rendered impure." Referring to mechanical ventilation, Captain MacIlwaine said: "To force air into a place we desire to ventilate is to dilute the foul air of the interior; to extract, is to get rid altogether of the foul air, when a supply of pure air equal in amount will take its place. What I would call a system of ventilation would be an arrangement which would provide for the supply of the necessary amount of fresh air, and for the removal of an equal amount of fouled air. Provision must be made for supply and exhaust in equal quantities." Captain MacIlwaine made mention of the experiments made by the Sanitary Institute at Kew in 1878, historically known as the "Kew Farce," instituted for the purpose of determining the respective values of certain ventilators, when, as the result of their labours, the committee issued a report in which it was stated that an open pipe was the most reliable ventilator, and that other ventilators, therefore, need not be employed. The lecturer stated that one of the committee had told him that these results were more than verified, and added, in refutation of the idea that a simple opening through the roof could possibly secure proper or reliable ventilation: "One word here as to the prevalent, but, as I understand it, mistaken notions which are current as regards the principles of ventilation. In a room, or other like place, the heated air rises; the general idea is that in order to get rid of this heated air it is only necessary to open communication with the outer air at the top of the room, and that it will there escape; but this is certainly a mistake, as is well pointed out by Mr. Chalmers, of Glasgow, who, in a lecture delivered at Glasgow in 1890, said that when under these circumstances the heated air met the outside air, it merely shook hands with it, as it were, gave out its latent heat, increased its specific gravity, and then fell. Another point in this connection is this: Where are the impurities to be found in a badly-ventilated compartment? There is a very general idea that CO₂, being heavier than air, falls, and is always to be found near the floor or low down, and arrangements are sometimes made to exhaust the air from this part in consequence. There can, I think, be no doubt that it is quite erroneous to suppose that the CO₂ falls. I have the opinions of two professors of chemistry on the matter, and both say that, owing to the laws of the diffusion of gases, the CO₂ in any place, however badly ventilated, will be found to be

practically equally distributed in all parts of the place." In conclusion, Captain MacIlwaine recommended that ventilators should be as numerous and as large as possible, and that where mechanical ventilators were used, it should be made sure that they really draw the foul air from the places they work in, and that they are not employed merely to churn the air in their immediate neighbourhood. A discussion followed, in the course of which a representative of Messrs. Robert Boyle and Son made the following remarks: With respect to the quantity of air that should be supplied per hour for each adult in a building, the system of ventilation in use must determine that. With the old-fashioned method, plain open pipes, with a cover on the top to keep out the rain, the downward current usually found to exist in these shafts, and which cooled the ascending vitiated air, forcing it down again to be rebreathed, it was necessary to make very ample provision indeed to dilute to a fairly healthy standard the vitiated air in the building, which was not permitted to escape at the proper level—that is to say, above breathing level—but had to find its way out as best it could in other directions. With the improved methods of ventilation now employed, the hot, vitiated air, which naturally ascends to the ceiling, is drawn off as rapidly as it is generated, and is not permitted to return to breathing level again, so that pure air, supplied through the air-inlets provided, is always maintained at that level. Under these conditions—which, with the Boyle system of ventilation, are guaranteed—150 to 200 cubic feet of air per hour per person are amply sufficient for all ordinary requirements. The method of admitting air referred to by Captain MacIlwaine as the invention of Mr. Tobin is very old indeed. The library at the British Museum was ventilated on that principle when built, and many other buildings. This method of admitting air also formed part of the "Boyle System" for many years before Mr. Tobin's name was known in connection with it. With regard to the experiments conducted at Kew in 1878 by the Sanitary Institute of Great Britain, the *Times*, which was the organ selected by the Institute to make public the results, condemned the experiments in the strongest manner, stating that "the method of testing was incorrect, and therefore the tests are valueless. . . . Neither in the case of either of the cowls nor the tubes was their true value as extractors ascertained." This opinion was endorsed by all the scientific and other journals which noticed the experiments. Sir Douglas Galton, President of the Sanitary Institute, referring in one of his published works to the utility of open pipes as ventilators, says: "In consequence of the numerous causes of disturbance enumerated above, this method of extraction, when applied to a house, cannot be relied on to act on all occasions with certainty as an extraction shaft." This condemnation of the open pipe as a ventilator is endorsed by all scientific men who have studied the matter, and is confirmed by the various experiments conducted in this country by Mr. Hellyer and other practical experts. Mr. Smaile, the engineer to the Water and Sewerage Board, Sydney, Australia, to quote from an article which lately appeared in the *Building News*, "instituted lengthened experiments with a view to test the exhausting power of the different ventilators submitted, but like the experiments carried out by the Sanitary Institute at Kew, the results were of an inconclusive nature, for although the majority of the ventilators were found to be better exhausts than a plain open pipe, yet when tested against each other in certain situations, conflicting results would be obtained when tried in other positions, though in each case the ventilators were fixed clear of all external obstructions. These tests afford an additional proof that it is impossible to correctly ascertain the comparative exhaustive power of different ventilators, especially when of a small size, by simply placing them on the tops of pipes in certain situations, and testing them with an anemometer or the water test, and they endorse the results which have invariably been obtained from experiments carried out at different times in this country." The late Mr. William Eassie, C.E., who formed one of the committee who tested the ventilators at Kew, was in the habit of using exhaust ventilators regularly up to the time of his death, and we supplied him with many hundreds of the air-pump ventilators for the ventilation of soil-pipes, &c. In one case—a nobleman's mansion situated in the North of England—Mr. Eassie stated

that, in deference to the desire of his client, no soil-pipe ventilators were used, the plain open pipe only being employed. The smells, however, at the ground level were found to be so intolerable that air-pump ventilators had to be applied, when the smells at once ceased, and did not recur again. This is only one of thousands of instances that might be quoted to prove the superiority of a properly-constructed exhaust ventilator over a plain open pipe, and which endorses the statement made by Captain MacIlwaine respecting the experiences of Mr. Chalmers, of Glasgow, who found that a simple opening through the roof merely permitted the cold external air to descend. This is the experience of all who have ever tested a plain open pipe in a heated building, it being almost always found necessary to close up such a pipe to stop the disagreeable and dangerous draught. The tests made by the Sanitary Institute could not, in any case, permanently determine either the merits or demerits of exhaust cowls as compared with an open pipe, as improvements are constantly being effected in these ventilators, and those in use to-day would be quite different from the ventilators tested by the Institute, even though the experiments might have been extended up to a recent date; therefore for all practical purposes they could prove of no value whatever, as they could only profess to demonstrate what was the value of certain ventilators at one time, but not what their value is now, which, after all, is the only thing the public is concerned with. With respect to mechanical ventilation, the system applied at the New London Law Courts is a notorious example of the failure of that method of ventilation to give satisfactory results, though everything that money and skill could do to make the mechanical ventilation a success has been tried.

A vote of thanks was accorded to Captain MacIlwaine at the conclusion of the proceedings.

JAPANESE STENCIL DESIGNS.

[WITH PHOTO-LITHOGRAPHIC ILLUSTRATIONS.]

MR. ANDREW W. TUER, F.S.A., has just published a very practical volume entitled "A Book of delightful and strange Designs, being One Hundred facsimile Illustrations of the Art of the Japanese Stencil Cutter," and by permission of the Leadenhall Press, Limited, we are enabled to present our readers to-day with a selection of patterns reproduced to a smaller scale, among our lithographic illustrations. As a frontispiece a real Japanese stencil plate is added, thus enabling the reader to realise exactly how such extremely delicate design is managed in decorating the cotton or crepe fabrics which are so largely used by the Japanese in the costume of both men and women. These plates are generally made, Mr. Tuer tells us, of disused documents, for the thrifty children of the Luminous Land waste nothing; and these plates form part of the working tools or stock-in-trade of the journeyman printer or decorator of cotton goods. The stencil plates made for sale in European markets by Japanese speculators are, like most things, manufactured simply to sell, and not for use, generally of a very ordinary and inferior kind, and, as a matter of fact, genuine stencil plates in Japan are no more a marketable commodity than the holed loom cards or engraved wooden blocks of English colour printers are marketable at home. The ceramics, enamels, metal-work, and general ornament of the Japanese have already been described, illustrated, and ingeniously analysed by several capable writers from various points of view, while the fashionable craze for Oriental goods of a cheap character has tended to weary the public taste for a time in so far as it is superficially interested. To the student of design and lover of real art-work the care for design of intrinsic merit remains as keen as ever, and the true artist is ever ready to acquire knowledge and examine beautiful things. This being so, we are not surprised to learn that Mr. Tuer's pattern pages have already met with an appreciative reception, and his fanciful inscription in which he dedicates his book "to that most capricious, never-to-be-understood, weathercocky, provokingly incorruptible, and absolutely necessary person, The Gentle Reader," is indicative of the good humour of the author. He does not confine his attention to such light fancies only, for he tells us several practical things. Thus he tells how the cobweb-like threads of silk which are introduced into the more

delicately designed pattern plates are manipulated, stretching as they do at regular intervals from top to bottom and from side to side, forming a strong net of so fine a texture that the stencil brush ignores them and leaves no mark of their presence. As they are incorporated with the paper substance, it seems evident to the uninitiated that no workman, however skilled, could cut the pattern without severing them. The nut on the face of it looks uncrackable; but on closer inspection it will be seen that some very fine parallel marks are made upon the blank margins of the stencil-plates corresponding to the threads inside the paper and running through the designs. Still, the art of stencil cutting must be an extremely delicate and difficult task. This is the *modus operandi*. The artist-workman takes some half-dozen sheets of tough paper made of mulberry fibre prepared with the juice of persimmon, and waterproofed with a hard-drying oil. On the top he places the design drawn with ink. The sheets firmly secured, he begins cutting with a long, thin knife, slowly cutting through the pile of paper, following the curves of the pattern, the holes and dots being punctured with a clean-cutting punch. Two of the sheets are then damped so that they may expand, and—what is of equal importance—contract equally in drying. One of these is laid down flat, and covered with adhesive material. The threads are then one by one put in position, the end sticking on to the margins. The joining of the two plates inclosing the threads is so absolutely perfect that a strong glass fails to disclose any sign of overlapping or unevenness. Mr. Tuer describes the further process of manufacture, and gives much information from various sources of the customs and costume of the Japanese. A population of one and forty millions takes some dressing. Commencing from the top left-hand corner of our sheet, No. 1 is the Hawthorn; No. 2, an alternative flower pattern; No. 3, Feathers; No. 4, Wild rose; No. 5, Tits or birds; No. 6, Fret pattern; No. 7, Running fanciful design, with birds and cages introduced; No. 8, Bamboo doubled round to form rings in the pattern; No. 9 (the first of the large patterns), is of bamboos conventionalised; No. 10, Splashed design; No. 12, Crayfish; No. 13, Carp and catarract; and No. 14, Hairy-tailed tortoise (hairy tail, special mark of longevity). Mr. Tuer has printed his introduction in French and German, as well as in English, and we need hardly say that the types and execution are all that could be desired from the machines of the Leadenhall Press, which in the past has determined no mean standard of excellence.

COLONIAL MEMBERSHIP OF THE SURVEYORS' INSTITUTION.

THE Council of the Surveyors' Institution have during the past twenty years received many applications from surveyors holding official positions in the British colonies and dependencies to be elected members of the Institution, but it is only recently that they have been in a position to entertain such applications for admission without examination under the provisions of a by-law which states that "it shall be in the power of the Council, by a vote of not less than three-fourths of the whole Council, to dispense with an examination in favour of any candidate of exceptional standing as a surveyor or of a candidate holding an official appointment as a surveyor in any of the British colonies or dependencies who shall have passed such other examination as the Council may accept in lieu of the said examination." Admission to every grade of members, except to the limited class of non-professional Associates, can now only be obtained by a searching examination, for which colonial surveyors could not be expected to present themselves. Under the above by-law the Council of the Institution are prepared to entertain applications for admission to membership without examination from surveyors holding official positions in India, the Australasian Colonies, Canada, British Guiana, the West Indies, Cape Colony, and the Straits Settlements, where it is understood that candidates for such appointments are required to pass an examination, which can be accepted in lieu of the professional examination of the Institution. Candidates will be eligible who have passed examinations qualifying them as authorised licensed surveyors, or as Crown surveyors, or Surveyors-General in any of the foregoing colonies and dependencies. While the diploma will bear on it a notification that it applies solely

to the colonies, the privileges of colonial members will be identical with those of all other members. We understand that the Colonial Office have considered this new departure in the Surveyors' Institution of sufficient importance to forward copies of the Council's memorandum explaining its provisions to every British colony throughout the world.

Extra length over 20ft. add 5s. per foot fixed for the 56lb., and 4s. fixed on the 30lb.			
CELLAR HOISTS, fixed, exclusive of any excavating—			
Table	2ft. 6in. by 2ft. 6in., steps 1ft. 6in., height of basement 10ft., weight 2 to 5cwt.	ditto	25 10 0
Ditto	3ft. 6in. by 2ft. 6in., and 1ft. 6in. steps, to raise 5 to 10cwt.	ditto	32 10 0
Ditto	3ft. 6in. by 3ft. 6in., steps 2ft., load 15 to 20cwt.	ditto	37 10 0
CELLAR HOISTS, fixed, but exclusive of any excavating—			
Platform	2ft. 6in. by 2ft. 6in., height of basement 10ft., load 2 to 5cwt.	ditto	31 10 0
Ditto	3ft. 6in. by 2ft. 6in., load 5 to 10cwt.	ditto	37 10 0
Ditto	5ft. 6in. by 3ft. 6in., load 10 to 15cwt.	ditto	48 10 0
HOSPITAL AND INFIRMARY LIFTS, fixed—			
Cage	6ft. 6in. by 3ft. 6in. by 6ft. 6in. inside, 80ft. high, to carry 5cwt.	ditto	70 0 0
Ditto	7ft. 6in. by 4ft. 6in. by 6ft. 6in. inside, 40ft. high, to carry 5cwt.	ditto	80 0 0
Ditto	7ft. 6in. by 5ft. 6in. by 6ft. 6in. inside, 45ft. high, to carry 7cwt.	ditto	99 0 0
FURNITURE LIFTS, fixed—			
Cage	4ft. 6in. by 3ft. 6in. by 5ft. 6in., to raise 5cwt., height 20ft.	ditto	42 10 0
Ditto	5ft. 6in. by 3ft. 6in. by 7ft. 6in., to raise 5cwt., height 20ft.	ditto	47 10 0
	Safety apparatus extra	ditto	5 0 0
Ditto	5ft. 6in. by 4ft. 6in. by 7ft. 6in., to raise 5cwt., height 20ft.	ditto	51 0 0
	Safety apparatus extra	ditto	5 5 0
Ditto	6ft. 6in. by 4in. 6in. by 7ft. 6in., to raise 7cwt., height 30ft.	ditto	53 10 0
Ditto	6ft. 6in. by 4ft. 6in. by 7ft. 6in., to raise 7cwt., height 30ft.	ditto	56 10 0
	Safety apparatus extra	ditto	5 10 0
Ditto	7ft. 6in. by 4ft. 6in. by 7in. 6in., to raise 8cwt., height 40ft.	ditto	62 10 0
	Safety apparatus extra	ditto	5 10 0
Ditto	7ft. 6in. by 5ft. 6in. by 7ft. 6in., to raise 10cwt., height 40ft.	ditto	67 10 0
	Safety apparatus extra	ditto	6 0 0
WAREHOUSE OR FACTORY LIFTS, driven by belt with gearing on top floor, fixed—			
Cage	3ft. 6in. by 2ft. 6in. by 6ft. 6in., load 5cwt., to travel 20ft.	ditto	75 0 0
	Safety apparatus extra	ditto	5 0 0
Ditto	3ft. 6in. by 3ft. 6in. by 8ft. 6in., load 10cwt.	ditto	85 0 0
	Safety apparatus extra	ditto	5 0 0
Ditto	4ft. 6in. by 4ft. 6in. by 8ft. 6in., load 15cwt., to travel 30ft.	ditto	100 0 0
	Safety apparatus extra	ditto	7 10 0
Ditto	4ft. 6in. by 5ft. 6in. by 8ft. 6in., load 20cwt.	ditto	121 0 0
	Safety apparatus extra	ditto	10 0 0
HYDRAULIC AND CONTINUOUS LIFTS, for passengers, will require special estimates, as the space, position, height, &c., varies so much.			
WAREHOUSE HOISTS, unfixed—			
To lift 9cwt. (to hang under ceilings) ...	ditto	10 10 0	
Ditto 5cwt. ditto ditto	ditto	11 10 0	
Ditto 8cwt. ditto ditto	ditto	13 10 0	
Ditto 10cwt. ditto ditto	ditto	16 10 0	
CRANE HOISTS, unfixed—			
To lift 2cwt., size of barrel 18 by 6	ditto	12 0 0	
Ditto 5cwt. ditto 24 by 6	ditto	15 0 0	
Ditto 10cwt. ditto 30 by 8	ditto	25 0 0	
Chain per foot, 7d., 10d., and 1s. 1d.			
Rope per foot, 4d.			
To lift 2cwt. (double) barrel 18 by 6	ditto	21 0 0	
Ditto 5cwt. ditto 24 by 6	ditto	24 0 0	
Ditto 10cwt. ditto 30 by 8	ditto	35 0 0	
POWER HOISTS, unfixed—			
To lift 5cwt., barrel 18 by 7½	ditto	17 10 0	
Ditto 8cwt. ditto 24 by 7½	ditto	20 0 0	
Ditto 10cwt. ditto 30 by 7½	ditto	22 10 0	
Ditto 10cwt. ditto 30 by 7½ strong	ditto	30 0 0	
Ditto 20cwt. ditto 30 by 9	ditto	40 0 0	
Ditto 30cwt. ditto 30 by 9	ditto	50 0 0	
Ditto 40cwt. ditto 30 by 12	ditto	61 0 0	
ENCLOSURES for lifts—			
Match-board and 2 dwarf doors to 1ft. floor	ditto	7 10 0	
Ditto one door	ditto	5 0 0	
Enclosure of posts and 1 sliding balanced shutter of galvanised wire in deal framing			
	ditto	4 0 0	
Posts and rails only, with lifting-bar	ditto	1 5 0	

THE SOCIETY OF ENGINEERS.

At a meeting of this Society, held on Monday week, Mr. Joseph William Wilson, junr., president, in the chair, a paper was read by Mr. A. G. Drury on "The Shortlands

and Nunhead Railway." The railway, which is a double line, commences by a junction with the Chatham Company's main line at Shortlands, passes through open country for the first half of its length, then runs through the suburbs of Catford and Brockley, and terminates by a junction at Nunhead station, having crossed a branch of the S.E. Railway, as well as the L.B. and S.C. Railway's main line, on the route. The length is 4½ miles. Attention was drawn to the fact that the line having been laid out to suit the views of the landowners, has not been laid out perhaps in the best way from an engineering point of view, also that as some of the estates passed through are about to be developed as building properties, the accommodation bridges are both frequent, and of a width or span suitable to future requirements. The elevations too, are of a more or less ornamental character, all of which requirements have added considerably to the cost of the undertaking. The number of bridges in the length is twenty-five, in addition to two short viaducts. Six of these bridges are for public-road crossings, two are over other railways, two are over streams, and fifteen are accommodation bridges. Brickwork and concrete has been used in the construction of the abutments and wing walls, the brickwork being in lias lime mortar except in the case of arches or in damp situations when cement mortar was used. The road bridges over the railway are chiefly of two types. One consists of a floor of plate girders resting on brick abutments, and spaced from 6ft. to 7ft. apart. Between the girders are jack arches which spring from their lower flanges; the top is levelled up with concrete and asphalted, the road metalling being laid above this. When the headway was very restricted another type of floor was adopted, which consisted of shallow troughs of a rectangular section, built with plates and 2in. bars, and placed parallel with the roadway. In this case the span was divided by columns placed between the lines of rails. The road bridges under the railway consist of plate girders resting on brick abutments, with a floor of built-up troughs. The bridges over the two railways crossed, of 163ft. 6in. and 110ft. spans respectively, consist of N-truss girders resting on brick abutments. At Catford two short brick viaducts, one 620ft. long, the other 200ft. long, carry the line through building property. The stations are five in number. The booking offices are all built of red bricks, with tiled roofs, and stand on the level of the adjacent roadways, being connected with the platform by covered stairs and galleries. The works have been carried out under the direction of Mr. John Wolfe Barry, M.I.C.E., the author acting as resident engineer in charge. The contractors were Messrs. Lucas and Aird, who were represented on the ground by Mr. John Blue, and latterly by Mr. Charles F. Day.

The thirty-eighth annual meeting of this society was held on Monday. The chair was occupied by Mr. Joseph William Wilson, junr., president. The following gentlemen were elected by ballot as the council and officers for 1893—viz., as president, Mr. William Andrew McIntosh Valon; as vice-presidents, Messrs. George Abraham Goodwin, Henry Faija, and William George Peire; as ordinary members of council, Messrs. R. W. Peregrine Birch, Chas. Claude Carpenter, Samuel Herbert Cox, Charles Gandon, Thomas Bell Lightfoot, Perry Fairfax Nursey, William Bradford, and George Maxwell Lawford; as hon. secretary and treasurer, Mr. Alfred Williams; as joint honorary auditors, Messrs. Alfred Lass, F.C.A., and Samuel Wood, F.C.A.

The annual dinner of the above society took place at the Holborn Restaurant on Wednesday. The President, Mr. Joseph William Wilson, junr., occupied the chair; and those present included Mr. W. A. McIntosh Valon (President-elect), Mr. Henry Adams, Mr. Jabez Church, Mr. Charles Gandon, and Professor Robinson (past Presidents); Mr. G. A. Goodwin (Vice-President), Mr. S. H. Cox, Mr. Henry Faija, Mr. G. M. Lawford, and Mr. W. G. Peire (members of Council); Mr. Alfred Williams (hon. sec. and treasurer), and Mr. G. A. Pryce Cuxson (secretary); Mr. Worby Beaumont, Colonel Harding, Mr. G. T. Rait, and Mr. J. W. Wilson. The chief toast of the evening, "The Society of Engineers," was proposed by Mr. Henry Faija, coupled with it being the names of the President, the Hon. Secretary and Treasurer, and the Secretary. In replying to the toast, the President enlarged upon the rapid pro-

gress of the Society, both financially and numerically. At the last annual dinner the year's increase in membership had been stated at 8 per. cent., and the increase for 1892 had been equally good. The membership was the highest yet attained in the 38 years' history of the society. This satisfactory state of affairs was due to several causes: the papers read at their ordinary meetings were carefully selected; the meetings had been very well attended; and the discussions had been increasingly practical and valuable. The professional visits had been this year popular and well-supported. They included the Tower Bridge, the South Metropolitan Gasworks at East Greenwich, the Kingston Sewerage Works, the South-west and Vauxhall Waterworks at Hampton, Messrs. Willans and Robinson's Works, Thames Ditton, and the Great Eastern Railway Locomotive Works at Stratford. The progress of the society was largely due to the unremitting labours of the council generally, and in an especial degree to their hon. secretary and treasurer, Mr. Alfred Williams, and to the business capabilities, tact, and energy of their secretary, Mr. Pryce Cuxson. The secretary also responded.

BOOKS RECEIVED.

By far the best and cheapest official catalogue of a public art collection we have yet seen is that prepared by Mr. Whitworth Wallis, F.S.A., the energetic keeper of the Birmingham Museum and Art Gallery, descriptive of the collections under his charge. In a sixpenny handbook Mr. Wallis gives readable notices of all the artists whose works are on view, arranged for facility of reference in alphabetical order, and these are interspersed by no fewer than 46 full-page illustrations of the permanent collection of paintings and statuary in the Art Gallery, and of the pictures at Aston Hall. The collections include representative landscapes by David Cox, and other works by Rossetti, Holman Hunt, Burne Jones, and Madox Brown, as well as examples of the older British masters, such as Bonington and Morland, and pictures by Leighton, Watts, and Millais. Sight measurements of the pictures add to the value of the handbook. We have also received the *Illustrated Catalogue to the Glasgow Art Galleries*, compiled by Mr. James Paton, superintendent of the Galleries and of Kelvingrove Museums, which is illustrated with a score full-page colotype reproductions of the more important and representative works of the old masters under their charge. The Glasgow Galleries of Art owe their origin, we are told, to a local coachbuilder and magistrate, Archibald M'Lellan, who acquired a collection of Continental pictures which became the nucleus, and is still the most considerable portion of the contents of the gallery. To these pictures, acquired by the corporation in 1856, have been added by bequests the collections formed by William Ewing and J. Graham Gilbert, R.S.A. These three bequests include 460 pictures, and the list has since been swelled by donations and legacies by about a hundred works of art, the present catalogue enumerating 561 pictures, besides 99 busts and other examples of sculpture. Mr. Paton gives brief biographical accounts of artists in an alphabetical list, and descriptions of the works. The good examples thus set by Mr. Wallis at Birmingham and Mr. Paton at Glasgow should be followed by the National Gallery and South Kensington authorities. We have not seen a guide-book of any kind, illustrated or otherwise, to the Diploma Gallery at Burlington House, while that to the Soane Museum needs revision, and the cuts might be improved and modern process-blocks introduced—a hint to the new curator. —*Poems in Petroleum* are the collected works of J. CAMERON GRANT, and will add to his rising reputation. His chief power is as a word painter, and some of his descriptions of South American life and scenery have much picturesque and vigour; the fault is a too frequent imitation of Tennyson's mannerisms and favourite metres. The new customary tribute to the late poet laureate, with which, as a matter of course, the volume closes, is beyond the average of these effusions. —*Quantity Surveyors' Tables and Diary for 1893* (London: Metchim and Son) is as handy a pocket calendar and remembrancer as any issued. The price is only sixpence. —*Practical Electric-Light Fitting*, by F. C. ALLSOP, author of *Telephone Construction*, &c. (London: Whittaker and Co.), follows the lines of the author's works on Electric Bell Fitting and

Telephones. As the author is a manufacturing electrician, the book is thoroughly practical, and is an amplification of a series of articles published in the *English Mechanic*. The author deals with the subject of supplying electricity from central stations to houses. Like a gas company, the electric-light company supply the electric current, the consumer making the connection to his building, which is done for him by an electric-light engineer. The laying on and fitting up is very important, and, as Mr. Allsop points out, unless the wiring is done by an experienced electrician disastrous effects follow. The directions given for wiring and fitting up houses and the laying of private installations, the remarks on main switches, switch boards, and branch switches are useful, and the points to be attended to are clearly stated. The want of ample contact surface, for example, is likely to lead to over-heating of switch, and other troubles. Several forms for obviating this weakness, often caused by wear of the switch, are to be found, as in those which automatically compensate for wear; several kinds of switches are illustrated. The details of fuse-boards, ceiling roses, wall-plugs, are considered, and various patterns given. Incandescent lamps and holders, arc lamps, pendants, brackets, are severally described and illustrated by carefully engraved examples. The modes of wiring floors and walls, moulded casings for wires, damp walls, ceiling casings, and other details receive particular attention, and the chapters discussing them ought to be read by every architect and engineer. The concluding chapters discuss circuit arrangements, testing, fitting, fire office rules, private installations, &c. The author's book gives information about, and supplies just those details of electric-light fitting which architects ought to have before they write their specifications. —*The Carpenter and Joiner*, by various authorities, edited by Robert Scott Burn, with folding plates and illustrations (London: Ward, Lock, Bowden, and Co.) is another volume of the technical series which these enterprising publishers are bringing out. The contents of this volume originally appeared in the "Technical Journal and Industrial Self-Instructor," but the compilers have added thereto a section on timber which will be found to deal pretty fully with the subject. The paragraph or sectional form of arrangement has been adopted instead of chapters, and the work is copiously illustrated by woodcuts and 207 folding plates, showing every kind of simple timber construction and joinery. As an elementary introduction to the subject of carpenter and joiners' work we can recommend the work to the workman and student. The sections on roofing joints and framing and strengthening of beams give a very complete description of the joints used, and are well illustrated. —*The Principles of Pattern-making*, by a Foreman Pattern-maker (London: Whittaker and Co.), has been written specially for apprentices and students in technical schools, and for this purpose the book is well suited. The types or examples selected are those generally required in the shops. Thus bracket-making, methods of jointing to enable the patterns to deliver from their moulds; modes of casting wheels, chimney bases, steam-chests, boxing up, swept work, engine cylinder, gear wheels, and other examples of pattern-making for the engineer's shop are explained and illustrated on the simplest principles. The chapter on "Constructional Joints" will be found of service to architects as well as engineering students. The tools and materials used are described, and there is a good glossary of technical terms at the end. —*The Engineering Magazine*, New York, for November, contains several interesting articles, one on "Light in Tall Office Buildings," by Mr. Dankmar Adler, illustrated; "City Hall Architecture," by Mr. Barr Ferre, illustrated; in addition to several engineering subjects of industrial interest. The present number is certainly much above the average of American engineering journals. —*The "Driquo" Blotting Case* (London: Spicer Bros., Limited) is an elegant and useful desk accompaniment, filled with an entirely new production in blotting paper, which well merits its name, for it is the most absorbent we have ever tried. It is also the most economical, for it blots equally well when covered with ink as when new. The new "Driquo" blotting paper is kept in white and pink colours, and in extra thick substance. We strongly recommend all readers to try a few quires. We much doubt if they will ever use any other afterwards.

WEIGHT OF CROWDS.

VERY contradictory statements of weights on floors are to be found in tables and text-books, in some cases the disparity showing a ratio of 4 to 1. It seems extraordinary that so great a diversity of weights should be possible. The engineer and architect are often perplexed by finding no satisfactory evidence to guide them. An instance of this diversity was given by Professor Kernot in a paper lately read before the Victorian Institute of Engineers. The author gives, in tabular form, a few examples of the weight of crowds, and the names of authorities making them. Thus one estimate quoted as French practice, by Stoney and Trautwine, gives 41lb. per square foot as the weight of a crowd. Hatfield, in "Transverse Strains," gives 70lb.; Mr. Page, engineer to Chelsea bridge, 84lb.; Mr. Nash, architect of Buckingham Palace, quoted by Tredgold, 120lb.; Mr. W. N. Kernot, at Working Men's College, Melbourne, puts the weight at 126lb.; Professor W. C. Kernot, at Melbourne University, gives it as 143.1; and Mr. B. B. Stoney, in his work on Stresses, as 147.4lb. per square foot. These statements vary to a degree which is quite perplexing. Professor Kernot criticises these statements, and shows that the space occupied by soldiers as taken by Hatfield in his investigation is not that of a crowd. The soldiers are arranged in lines at a distance apart to allow room for knapsacks, weapons, and other accoutrements; but a crowd is a body of men forced together by pressure into close contact. An average man in a crowd, Professor Kernot says, occupies a space little, if any, exceeding one square foot. Other results are also taken to task as being below the truth. Tredgold's 120lb. is considered the first on the list worthy of consideration. The last stated weight is considered the most conclusive. Mr. Stoney's experiments were conducted with precision, and resulted in a little more than one man per square foot, giving a weight of 147.4lb. per square foot. Prof. Kernot concludes, a dense crowd of well-grown men is proved, by his own and Mr. Stoney's experiments, to weigh from 140lb. to 150lb. per square foot.

"HARD SILVER" PLATING.

THE "Arcas" process of plating with an alloy of silver and cadmium is especially adapted for the fittings of halls, churches, &c., as it does not tarnish so readily as either pure silver or electro-plate, and is easily cleaned by merely wiping over with a damp cloth, and rubbing slightly with a dry leather, none of the polishing powders being required. Its first cost is less than nickel or silver plating, and as it lasts much longer it is consequently cheaper to the extent of about 30 per cent. during its life, though only about 10 per cent. at first. It is harder than ordinary plating, but not so hard as nickel; it is, however, more durable, and holds with great tenacity to iron and pewter, as well as to the ordinary metals. In places where much gas is used, or the ornamental metal work is exposed, it is a great advantage for the "Arcas" metal that it is so easily cleaned and polished, while its colour is equal to that of pure silver. The works of the company are at 80-81, Turnmill-street, near Farringdon-road Station, and specimens there shown will give an idea of the great variety of work for which the process is suitable. It is the best plating for lavatory fittings, for all work exposed to the atmosphere, and is extensively used for electric-light fittings, bells, &c.

CHIPS.

An advertisement in the daily press announces that Mr. Fothergill Watson, of Mapperley-road, Nottingham, architect, has assumed and adopted the name of Watson Fothergill.

A brass tablet, placed on a slab of black marble, has been erected in the chancel of Bishopthorpe Church, York, as a memorial of the late Archbishop Thomson. The inscription is surrounded by a border, and surmounted by a shield, combining the arms of the late Dr. Thomson and those of the see of York.

The Royal English Opera House, built from Mr. T. E. Colcutt's designs two years since, was reopened as the Palace Theatre on Saturday. The interior has been rearranged and gorgeously decorated at a lavish expenditure, while the exits and corridors have been improved. Mr. Walter Emden, M.S.A., was the architect for the alterations.

THE LEANING TOWER OF SARAGOSSA.

"La Torre Nueva," as it was locally known, was one of the largest of the class of brick towers of Spanish workmanship but of Moorish character extant, and perhaps one of the most beautiful. It stood in the Plaza San Felipe, and two dates referring to its erection are mentioned—1497 and 1504—possibly its earliest foundation and final completion, although to an eye unfamiliar with this particular class of work an earlier date would at once suggest itself, for the whole of the detail is of the most simple character and design. Some few years ago a high, almost gaunt, timber roof or spire was removed, with a view to lighten the top structure; and a huge, finely cast bell, at least 6ft. in diameter, was destined to a similar fate; but, owing to its great bulk, the removal was not then effected. The tower, which leaned nearly 10ft. out of the perpendicular, was 70 metres high (230ft.), and an octagon of 42ft. at the base, external dimension. For the first two stages the walls were, on the side to which it leaned—that is, the south, 18ft., but on the north only 12ft.; the extra thickness on the south was added in 1860, when the tower was generally overhauled. The central stairway in these two stages is 12ft. diameter, but less than 4ft. stair; above this level the staircase was built in the thickness of the tower walls, the central portion being carried up a closed well with 2ft. walls. The external walls at this point were 5ft., decreasing to 3ft. at the top. The destruction was confirmed in May of the present year, and operations were to commence in June, though, I believe, nothing was really done until three months later, and it is now doubtful if a single brick (which, by the way, were 1½ in. by 13 in.) could now be found.—HEBER RIMMER.

OLD BABLAKE AND BOND'S HOSPITALS, COVENTRY.

THESE sketches, by Mr. G. R. Webster, are taken from his recently issued "Coventry Portfolio,"* which comprises a book of 31 drawings of picturesque antiquities in that historic city. The experiences of the author, who acted as clerk of the works under Mr. J. O. Scott during the restoration of St. Michael's steeple, has enabled him to give some interesting details, and he shows the great tower during restoration and after. The sketches which we have chosen may be taken as fair samples of Mr. Webster's studies, which have had evidently no mean share of his care and personal interest in the work. Bond's Hospital was built for ten men and one poor woman in 1506 by Thomas Bond, Mayor of

Coventry, in 1497. The front of the building, which forms the north side of a quadrangle, is 120ft. in length. It was restored in 1820 very poorly, and has been altered since. The old Bablake Hospital forms the east side of the above-named quadrangle; and it was erected about the same time. The upper story over the cloister was originally an open gallery. Ford's Hospital, in a similar style, is the most celebrated of the series at Coventry.

ST. PHILIP'S CHURCH, STEPNEY.

We continue this week our illustrations of this church, of which Mr. Arthur Cawston is the architect. We have yet another sheet of details to publish, which will appear in an early number.

HOUSE NEAR ALFORD, LINCOLNSHIRE.

THIS residence is to be erected on a site between Alford and Sutton-on-Sea. The stone will be from the Ancaster quarries. The half-timber work will be teak framing with rough-cast panels. The woodwork will be finished with Stockholm tar. The roofs throughout will be tiled with Broseley brindled tiles, and the walls of servants' department and stables on first floor will be hung with similar red tiles. The interior of the hall will be panelled with oak, and the principal staircase will be also of that wood. The bay projecting from the side of the central portion of building above the hall will contain a staircase leading to the rooms in the roof. Mr. Horace C. Frasi is the architect. Both of the drawings shown on this sheet were exhibited at the R.A. this year.

HOUSE AT BOURNE END.

THIS house has recently been erected at Bourne End, near the river, as a summer residence for Mr. R. C. Lehmann, who is well known in boating circles. The house is faced with red bricks, and the roof covered with dark tiles. Internally, all the finishings of the woodwork are of pitch-pine. The works have been carried out in a satisfactory manner under a contract by Mr. E. R. Palmer, of Beckenham, Kent, under the personal supervision of Mr. Alex. R. Stenning, F.R.I.B.A., 121, Cannon-street, E.C.

JAPANESE STENCIL DESIGNS.

(For full description, see page 835.)

WOODEN MEMORIALS AT HAMMERFEST (FINLAND).

HAMMERFEST is the centre of the cod-liver oil trade. It is built entirely of wood, and has a population of about 3,000 inhabitants. It has the reputation for being the most northerly town in the world (70° 41' north lat.), and is reached after a sail of something over 200 miles north-east after crossing the Arctic Circle, which line of demarcation is somewhat north of the natural tunnel pierced through the Mountain-Isle of Torghatten. Hammerfest is situated at the end of a lovely bay, and upon one of the many islands that form, as it were, the outside defences for the Finnish mainland, and protect it from the encroachments of the ice-bound Arctic Ocean. In the summer time, for ten long and apparently endless weeks, the sun never sets; all that time it is perpetual day. At the present moment it is one continuous night there, a darkness of something like 1,700 successive hours. The town is, however, well lit all the winter by electricity. Water power being plentiful in Scandinavia, the electric light is both popular and economical. The cemetery at Hammerfest stands upon high ground just outside the town, and commands, in summer time, a grand sea view. It consists of a square plot of some two or three acres, inclosed by a low massive wall, made, like a Derbyshire one, of loose pieces of rock. This wall is 4ft. through and 5ft. high. In one corner there is a very rough mortuary chapel, little better than a sexton's tool-house. There are a few—a very few—simple granite memorials, and some ornamental iron crosses, none of them of any interest. It was the wooden memorials that struck me as particularly quaint, and worth a corner in my pocket book. To-day's sheet of illustrations gives half a score of them just as I saw and drew them a few months ago. They are all made of deal and painted, the main colours being black and white, mainly the latter. Some, however, were picked out in gold and colour, with very good effect. Many appeared to be nothing more or less than railway sleeper-like posts, stuck upright in the ground, painted white, and the name or initials of those lying below painted or carved upon them. These reminded

me of the earliest record of the rearing of any kind of sepulchral memorial in the world's history, the story of which may be found chronicled in the Book of Genesis. There we read:—"Rachel died and was buried on the way to Ephrath, which is Bethlehem, and Jacob set a pillar upon her grave, that is the pillar of Rachel's grave until this day."—HARRY HEMS.

GROUP OF FURNITURE FROM THE "JULIA BOYD" COLLECTION.

THIS sheet illustrates some of the furniture recently disposed of by auction by Messrs. Davison and Son, of the Academy of Arts, Newcastle-on-Tyne. The Gardrobe, which is 5ft. 6in. long and 6ft. high, is treated in the upper part with three long panels gracefully carved, and with quaintly shaped heads, beneath which are three smaller oblong panels, also decorated. Beneath these is a substantial plinth containing three drawers. The upper part opens with a door on either side of centre panel. It sold for £9 15s. The Elbow Chair is richly but not deeply carved in the back, and the curved pediment is fluted; £5 10s. was the price accepted for this piece of furniture. The Settle (sold for £8 10s.), a simple but good piece, has a lift-up seat, the space under being utilised as a chest. The small circular Table (£3), with turned legs and fall-down flap, makes a pleasing addition to this group, which contains some typical examples of Old English furniture, and, like most bygone work of this kind, all are executed in oak. The sale was largely attended and very successful, and realised £4,000.

CHIPS.

The final obsequies of the late Prof. Solomon Corrodi, who was styled the father of the water-colour landscape painters in Rome, took place on Saturday, the remains having been brought from Como, where M. Corrodi died suddenly in July last.

An inquiry was held at the town hall, Barnsley, on Friday, in reference to the application of the town council for increased borrowing powers to the extent of £10,000 on waterworks account. Major-General C. Phipps Carey, R.E., one of the Commissioners of the Local Government Board, conducted the inquiry, and evidence in support of the application was given by Mr. H. Horsfield, town clerk, and Mr. J. H. Taylor, borough surveyor.

Colonel J. O. Hasted, R.E., held an inquiry on behalf of the Local Government Board at the Castleton local board offices, on Friday, into the application of the Castleton local board to borrow £22,000 for works of sewerage and sewage disposal. Mr. James Diggle, C.E., the engineer to the board, explained the scheme, which, he said, would provide for the requirements of a population of 12,000, the present population being 5,700.

The director of the National Gallery has purchased a picture, "La Jeune Dame au Clavecin," by Jan Vermeer, of Delft. The picture formerly belonged to the French connoisseur Thoré ("W. Bürger"), who first brought into notice that great Dutch painter.

Prof. Begas's third model for the National monument of the late Emperor William, which differs materially from the first and second, has received the Emperor's assent.

On Saturday, at Honiton, Sir John Kennaway, M.P., opened a new schoolroom for All Hallows School. The new building contains a memorial window to the late Bishop Mackarness, of Exeter, the work of Mr. Drake, of Exeter.

The Gravesend school board have decided to have an open competition for designs for new schools to be built in Wrotham-road, and to accommodate 700 children in three departments. The buildings are to be of one story only, and the maximum cost is £6,000.

The authorities of University College, Bristol, have made arrangements for the delivery of a course of six Oxford extension lectures on "The history and principles of architecture," by the Rev. Dr. West, to take place after the Christmas vacation.

St. James's Cathedral, Townsville, Queensland, has been dedicated by Bishop Barlow. The complete design will cost £30,000. The only part now completed consists of the apse, chancel, and transept, the cost of which has been nearly £9,000. The architect is Mr. A. Blacket, of Sydney.

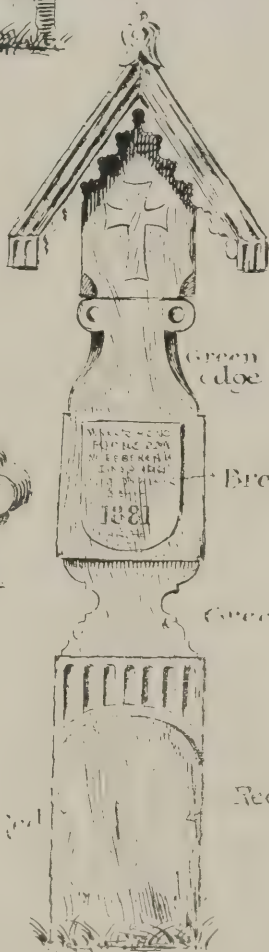

In the returns of attendances at the meetings of the City Court of Common Council, the lowest place as regards a corporator's suit and service is taken by Mr. Edward Blakeney T'Anson, F.R.I.B.A., F.S.I. (son of a recent president of the Institute), who is credited with having attended twice only and with having taken part in no division.

WAYSIDE NOTES.

IN the old days of Millbank Prison there was doubtless a goodly company of housebreakers, and in the closing days of the grim and ghastly old Penitentiary we find men of similar denomination gathering round. Only the difference between the two classes of housebreakers is rather marked. On the one hand we have the burglar fraternity, and on the other the professional "housebreaker" who contracts to take down old premises for or under the value of the materials therein. Round Millbank gathered these latter last Tuesday, and competed for the grimy remains of the building. That portion of the prison put up to auction as a heap of old building materials realised in all some £630. Among the "lots" were the slates on the roof of laundry, No. 1 Pentagon, £19 10s.; the whole of the brickwork, stone coping, and sills of the kitchen, oakum shed and shaft, £41, and so on, the prices seeming very fair considering that carting away has to be done, and that the "housebreaker" speculating in old materials is not in the position of the contractor who finds himself with old premises on the site of new works and materials thus ready to hand.

The value of the ss. *Eider* in public auction, after its wrecking on the coast of the Isle of Wight, is £8,000. The ship cost £100,000. As a sea-going vessel the *Eider* is evidently useless, else the purchasers have secured an extraordinary bargain.

The Chairman of the Peninsular and Oriental Steamship Company described, at a recent meeting of the Board of Management, the loss of the *Bokhara* as "an act of God." I thought that this old, meaningless phrase, good enough in darker ages, had long ago become obsolete. It is a nice, comfortable thing for the chairman of a steamship company, which has lost a vessel and, with the vessel, many human lives, to shift the responsibility on to God. Other persons might like to know a little about the condition of the skylights over the engine-room, &c., and why they were not so built and so protected as to be proof against giving way under any weight of water that can come aboard a ship sailing on the surface of the ocean, during even a Chinese typhoon. Blessings and fortunate occurrences people seem willing enough to refer to their own intelligence and foresight, while an accident, the result of human bungling, they would disown, and style, forsooth, "an act of God"!

The Labour Bureaux of Paris are institutions that deserve imitation in this city, and are especially apropos during the time of distress from want of employment. Eleven bureaux in Paris are maintained for the outlay of under a thousand a year. Employers are found to readily revert to the bureaux, and a large proportion of applications for work are satisfactorily dealt with. If only that such a system facilitates the distinction of the really poor, unfortunate, and deserving from the professional vagrant and loafer who never intends to do a stroke more work than he can help, it is a beneficial one.

In the matter of construction of the Blackwall Tunnel, the County Council's Bridges Committee had come to the conclusion that the advice of Sir Benjamin Baker and Mr. Greathed should be followed. The Council, however, have decided to appoint a special committee to consider the matter. What are the recommendations of the two eminent engineers consulted by the Council is not stated.

Tuesday's meeting of the Council was decidedly stormy, and the rational party displayed a bold front in the matter of wages and municipal building. Sir John Lubbock's remarks on these matters I would commend to the notice of readers. Said Sir John: "If the Council could not supervise the work, still less could they do it themselves; like Rehoboam of old, who rejected the counsel of old men for that of youth, the London ratepayers would pay dearly for the 'young' ideas of its County Council." Sir John further thought that they would make a great mistake in undertaking a gigantic building business, when they had questions to solve of the gravest importance, and which would tax, not to say overtax, their utmost energies. As to the proposal to pay any wages which any London trade-union chose to fix, this is, as Sir John Lubbock said, indeed absurd. Trade under such condi-

tions would soon dwindle away into something vastly worse than even its present stagnant condition. The fair-wage movement is a blessed movement; but there is just the danger of its proving a curse to the recipients of wages generally.

Mr. John Lobb's letter in Wednesday's *Times* should have been noticed, dealing, as it did, with the past building of board schools and the cost of school-building in the past.

The Great Eastern Railway Company propose further improvements at Lowestoft—probably in connection with the fishing industry. What is Yarmouth doing? I am told that the new harbour at Lowestoft is a much easier place for boats to enter in rough weather than the narrow river mouth at Gorleston. When the originator of the idea of a harbour at Lowestoft first brought forward the idea, it was at Yarmouth that he proposed to place the harbour. The Yarmouth townsmen, however, would hear of no alteration to existing arrangements; consequently, the harbour was built at Lowestoft. Since then the fishing trade at Lowestoft has developed, to the injury, necessarily, of that at Yarmouth. When will the Yarmouth Corporation awaken to a sense of the requirements of the day? As a well-wisher of success to the old town, I draw attention to this matter of the harbour that was proposed for Yarmouth and built at Lowestoft. Is there no improvement that Yarmouth can effect in its harbour accommodation? If there is, it is surely a duty of the Corporation to seek means of carrying it into execution.

Since writing the above I notice it stated in the report of the meeting referred to that the Lowestoft estimates are for the better accommodation of trawl-fishing, at a cost of £10,000, and alterations to the swing-bridge bringing the total cost up to £22,000.

Campanologists will have noticed the deplorable accident in the bell-chamber of the parish church at Presteign, Radnorshire, whereby a young man named George Vaughan lost his life. On Sunday evening the bells had been rung and left "set." On Monday afternoon Vaughan repaired to the bell-chamber to make some necessary alteration to the gear, and it is supposed that in the course of his work he dislodged one of the bells, causing it to swing over, and that, to save himself, he had clutched the wheel of another, and caused it to fall also. One of the bells had evidently struck him on the head, killing him instantly, his body being found astride a beam among the bells.

It is to be hoped that the Hilly Fields, near Deptford, will be secured as an open space. The ground will be a great boon to residents in the neighbourhood. GOTH.

CHIPS.

Two new bells have just been cast by Messrs. Mears and Stainbank, of London, to be hung in the tower of Winchester Cathedral, raising the peal from eight to ten. The new bells will be the trebles of the peal, and respectively weigh 784lb. and 628lb.

Two well-known Liverpool city churches will soon disappear—St. Andrew's, Renshaw-street, and St. Barnabas's, Rodney-street. The demolition will take place early in the New Year. The Liverpool city council are also taking steps for the removal of two other city churches—St. George's, at the top end of Lord-street, and St. John's, adjoining St. George's Hall.

The certificates awarded by the examiners for the winter term in the Crystal Palace School of Practical Engineering are to be distributed to-morrow (Saturday) by Mr. W. H. White, F.R.S., the Assistant Controller and Director of Naval Construction of the Admiralty.

A new retort-house and other buildings have just been added to the gasworks at the Pleck, for the Walsall town council. The contractors were Mr. T. Tildesley, of Willenhall, and Messrs. Rubery and Co., of Darlaston.

Archdeacon Palmes, of York, preached on Friday in the parish church at the village of North Dalton, eight miles from Driffield, the occasion being the unveiling of a new east window in three lights. The window is from designs by Mr. E. Burne-Jones, A.R.A., supplied by Mr. William Morris, of Merton Abbey Works, Surrey, and fixed by Mr. Stabler, Driffield, art decorator.

OBITUARY.

THE death is announced from Boston, U.S.A., of Professor Eugène Létang, who, for the past twenty years, has been the head and director of the Architectural Department of the Massachusetts Institute of Technology. M. Létang had been connected with the department almost from its foundation, and had contributed in a very great degree to its success. Eugène Létang, who was only fifty years of age, was born in the department of Nièvre, France, and was educated as an architect under M. Vaudemer. At the School of Fine Arts he was particularly successful, carrying off four medals and winning a high reputation for solid attainment, interrupting his work to aid in the defence of his country during the Franco-Prussian war of 1870-1. Soon after finishing his course at the Beaux-Arts, he was induced by Professor Ware to take charge of the instruction in architectural design in the Institute of Technology in Boston, Mass., and from that time, until a few weeks before his death, he was untiring in his efforts for the school. He was a firm believer in, and an ardent advocate of, classicism, simplicity, and careful proportionment. Outside of his school Professor Létang was known to comparatively few persons. He leaves a widow, but no children.

Mr. Abraham Smith, builder and contractor, Castle-street, Farnham, Surrey, died suddenly on Tuesday week. For six years he had been a member of the Local Board of Farnham, and was also a sergeant in the local volunteer corps, of which he was an old member.

The sudden death is also announced of Mr. Richard Kelly, builder, of Mexborough, near Doncaster. Mr. Kelly, who was in his fifty-third year, had carried out many important contracts in the neighbourhood of Doncaster, Swinton, and Mexborough.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

MANCHESTER SOCIETY OF ARCHITECTS (INCORPORATED).—A general meeting was held on Tuesday evening last at 36, George-street, at which Mr. J. Gibbons Sankey, M.A., was elected a Fellow, and Mr. Bernard H. Brameld an Associate. The third sessional paper was read by Mr. R. Knill Freeman, F.R.I.B.A., entitled "A Few Notes." A great variety of matters important to architects were referred to, including education, practice, competitions, &c., with much useful advice to the junior members. An interesting discussion of the paper was followed by a vote of thanks to the author.

SURVEYORS' INSTITUTION.—We are informed that 251 candidates have entered their names for the approaching examinations. Of this number 71 are candidates for the studentship, 133 for the Associateship, and 47 for the Fellowship, representing in the aggregate an increase of nearly 25 per cent. on the numbers of any previous year.

ARCHÆOLOGICAL.

ROMAN REMAINS AT SWAFFHAM PRIOR. — Extensive remains of Roman buildings have been found at Swaffham Prior, between Cambridge and Mildenhall. During the last three weeks there have been unearthed the foundation walls of one or two rooms, including a small hypocaust, with its firing door, and a considerable length of boundary wall towards the south. The room had a small apse of the usual kind facing the west. A similar apse occurs in the longer southern wall, and at two points within the walls there remain portions of a paving of ordinary terracotta *tessellæ*. Up to the present nothing has been found to give any clue to the date of the building, whether early or late in the Roman occupation; but there are records of the discovery of coins in the immediate neighbourhood dating possibly as early as 210 A.D. There is the usual abundance of broken pottery, fragments of flue-tiles, glass, and roof-tiles, and bones of oxen. The excavations are being conducted under the direction of Professor Hughes.

At the annual meeting of the Maidstone School of Art, held on Friday evening, it was announced that the corporation of that town had, after competition, selected the design of Messrs. Rack and Smith (both former students of the school) for the erection of a new school of science and art, to be built on the Museum grounds in St. Faith-street.

Building Intelligence.

ASTON.—The foundation-stone of a new technical school was laid on Friday. The building will have a frontage of 98ft. to Whitehead-road and of 90ft. to Ettington-road, and consist of three stories, with chief entrance at the angle. The accommodation of the basement will comprise a modelling-room, with recess for casting; engineering classroom, with engine-house and electric-lighting appliances adjoining; metallurgical classroom; plumbing workshop; laundry, having washhouse, drying-closet, and ironing-room; spare classroom, heating vault, stores, &c. The ground floor is to have a lecture-room, two rooms for elementary art, secretary's and curator's rooms, teachers' rooms, and four classrooms. On the upper floor is to be a chemical laboratory for 40 students, with preparation room, balance-room, teachers' room, and stores adjoining, a lecture-room, and also art classrooms. On each floor lavatory accommodation will be provided. At the rear of the premises a separate one-story building is to be provided for carpenters and joiners' work, and this will accommodate 60 students. The buildings will be warmed by low-pressure hot-water pipes, and electric light will be provided throughout. The style adopted is English Renaissance, with large windows. The main entrance block and the gables at the ends of the façades will be somewhat elaborated to give emphasis to the leading features of the design, but the whole of the building is to be solidly and substantially treated. The elevations are to be faced with pressed Stourbridge bricks, relieved with stone and terracotta. The amount of the contract is £5,545; the contractor is Mr. F. N. Stephens, Park-road, Aston, and the architect Mr. George H. Cox, of 28, Temple-street, Birmingham.

BATLEY.—The new public baths, the technical school, and the girls' higher grade school at Batley, are now all nearing completion. The new public baths, which have their frontage to Cambridge-street, are 134ft. by 126ft. The greater portion of the building is only one story high. There will be two swimming-baths. The first-class one will be 63ft. by 25ft. The second-class will be 75ft. by 30ft., and will have a spectators' gallery. Both these baths will be lined with glazed bricks. Twenty slipper baths are also to be provided. The architect is Mr. Walter Hanstock, Batley.—The new technical school stands within a short distance of the baths. The main entrance is in Cambridge-street. The chemical laboratory is being fitted up on the ground floor. On the first floor is a lecture-hall capable of accommodating 100 students. A spacious room will be used as a workshop. There will also be a number of class-rooms.—The location of the girls' higher grade school is Field Head. A similar school for boys will be provided hereafter by erecting a duplicate of the present structure. The style is Renaissance. In the centre is an assembly-room 40ft. by 30ft., with class-rooms on each side of it. At one end of the large room is a gallery. Mr. H. B. Buckley, architect, of Leeds and Batley, prepared the plans for the technical and higher grade schools, which were both illustrated in our issue of Jan. 15, 1892. The next public building erected in Batley will probably be a Town Hall. The present Town Hall is not adapted to its purposes. It was erected by a company, and some time ago it was taken over by the Corporation, which now uses the small rooms for municipal offices, while the large hall serves as a council chamber.

LEEDS.—Blenheim Chapel, in Woodhouse-lane, Leeds, which has been undergoing extension and improvement for some months, was formally reopened on the 1st inst. The alterations consist in the extension of the chapel in length the width of one bay, and an increase of 100 to the sitting accommodation; while the whole of the gallery has been re-seated and cushioned, and made equal to the seats on the ground floor. Special attention has also been paid to the heating and ventilating, the old hot-air apparatus having been taken out, the chapel and the whole of the premises being now heated with hot-water pipes, which have been laid by Messrs. Heaps and Co., of Huddersfield. Ventilation is secured by means of fresh-air inlets and by extracting the foul air by means of a ventilating shaft taken up the tower. The greatest improvements which have been made to the chapel are the entrances. A tower with a broad

spire has been erected on the corner of Blackman-lane. A porch the full width of the chapel, and an inner lobby 8ft. wide have been built on the chief façade. Wide stone staircases lead up to the galleries. The contractors were—Messrs. Nettleton and Sons, masons; Messrs. J. H. Atkinson and Son, joiners; Messrs. W. and C. Burdard, plumbers; Messrs. Atkinson and Son, slaters; Mr. Thomas Moore, plasterer; and Mr. C. Fenton, painting and decorating. Mr. W. A. Hobson, of Leeds, was the architect.

LIVERPOOL.—The new Victoria Building of Liverpool University College was opened by Earl Spencer on Tuesday. The western wing of the building contains the Tate library. A feature of the southern elevation is the Jubilee Tower, the clock and bells in which have been given by Mr. Hartley. In the east end of the building, on the upper floor, a semicircular theatre, with raised seats, has been constructed. The great hall, a chamber two stories in height, is 68ft. by 30ft. East of the hall, in the portion of the building placed under the large theatre, are the students' common-room and reading-room. The first floor contains classrooms (the largest of which is 43ft. by 22ft.), and one or two professors' rooms. Over the archway is a reading-room, connected with the senate chamber, which latter is 27ft. square. On this floor the ladies have a common-room and a reading-room. On the second floor the theatre and the library are situate, and the third floor is mostly occupied by the upper part of the library and the lecture theatre. The statue of Mr. Christopher Bushell, executed a few years ago by Mr. Bruce Joy, and placed in the great hall of the Free Public Library, William Brown-street, has just been removed to the new building. The building is fireproof throughout, the floors being of concrete, on an iron framework, supplied by Messrs. Handyside and Co. The cost has been £60,000. The general contractors were Messrs. Brown and Backhouse, and the whole of the works have been carried out under the supervision of Mr. Battye. Messrs. A. Waterhouse and Son are the architects, the design having been prepared by Mr. Waterhouse, R.A., in 1888.

KEIGHLEY.—At a special meeting of the Keighley Town Council, held on Friday night, it was decided, after a long discussion, "That a temporary hospital for infectious diseases be erected on the site of the proposed hospital at Woodhouse at an estimated cost of £650, and that Messrs. Judson and Moore, the architects, be instructed to proceed with the necessary work with all possible speed." The mayor explained that the temporary hospital would be of corrugated iron, lined with boards, with an accommodation for twelve beds. The cost of this would be £650. There would also be an outlay of £125 for road-making and drainage; but this would form part of the permanent scheme, for which Messrs. Judson and Moore's designs were adopted in competition two months since.

MANCHESTER CATHEDRAL.—The new pulpit in the nave of this cathedral has been formally presented by Mr. Chancellor Christie. The general design is Perpendicular, in harmony with the building. The pulpit stands on a substantial granite plinth, which supports the main shaft of alabaster and eight pillars of Victoria red marble. The capitals of the columns are of white alabaster, decorated with foliage and miniature heads. The pulpit itself is entirely composed of variegated alabaster, a cream-like white prevailing. The angles are filled in with six alabaster statuettes representing the Saviour and Apostles. Above the heads of the statuettes are carved canopies; while the cornice is finished with battlements. The staircase of nine steps, of York Greenmoor stone, is of variegated alabaster, filled with tracery work. At the termination of the hood-moulds are heads of different designs. At the foot of the staircase pedestals are placed, on which are angels, one bearing the coat-of-arms of Mr. Chancellor Christie, the other the coat-of-arms of the diocese of Manchester. The work has been executed under the direction of the cathedral architect, Mr. Crowther, by Messrs. Earp and Hobbs, of Manchester and London. One of the last important works of the Cathedral restoration—the erection of the new south porch and baptistery—is now practically completed. The porch is faced externally with Darley Dale stone, from the Derbyshire quarries of the late Sir Joseph Whitworth; and with Carlisle stone inside. The design is in accordance with

the general architecture of the cathedral. The adjoining new baptistery is quite a new feature in the church, the baptistery hitherto having been at the north-west end of the nave. In the interior of this baptistery, now just on the point of completion, the pavement immediately surrounding the font is of Roman mosaic. At the four angles are panels, representing the Four Evangelists, with the text "Baptising them in the name of the Father, of the Son, and of the Holy Ghost." Outside this panel the baptistery is paved with dove, red, black, and white marble. The font, which formerly stood near the north entrance to the nave, has been removed to the new baptistery. It may be here mentioned that this font was dedicated about 40 years ago. The carved oak cover over the font was presented to the cathedral 45 years since as a memorial of the late Mr. George Lings, many years comptroller and father of the present comptroller. The marble pavement, mosaics, &c., in the baptistery have been executed by Messrs. J. and H. Patteson, Marble Works, Manchester. This firm has also executed the marble and mosaic flooring throughout the building. The masonry of both porch and baptistery has been executed by Messrs. John Nicholl and Son, of Rochdale; and the whole has been carried out under the directions of the cathedral architect, Mr. J. S. Crowther. The total cost of these two works has been £5,100, the porch having cost £2,600, and the baptistery £2,500.

NEWCASTLE-UPON-TYNE.—The foundation-stone of the further extension of the Durham College of Science was laid on the 5th inst. by the Earl of Durham. The portion now in course of erection will about equal in bulk the portion first erected about five years ago. In the centre is the Royal Jubilee Exhibition Tower, which forms the permanent and only memorial of the Jubilee Exhibition. It is built from the surplus of the Jubilee Exhibition, and comprises a gateway surrounded by four octagonal turrets, each 95ft. in height, and surmounted by ornamental ironwork. The turrets are to be made to serve respectively for (1) chimney, (2) ventilating shaft, (3) experimental tower with a mercury column 100ft. high for testing gauges, and (4) coal-hoist and staircase. On one side of the gateway, on the ground floor, are the following:—Metallurgical laboratory and balance room, with furnaces adjoining the chimney shaft; engine and dynamo room, 40ft. long, 35ft. wide, and 21ft. high. Here, also, is the George Stephenson engineering laboratory—an apartment 123ft. long and 35ft. wide, with an annexe measuring about 90ft. by 10ft. This will contain a 100-ton testing machine, experimental marine engines, oil-testing machine, bar-testing machine, cement-testing machine, hydraulic and other dynamometers. On the first floor are—lecture-room, 35ft. square, building construction, &c.; lecture-room, 40ft. by 35ft., for engineering and naval architecture; engineers' drawing office and model-room, 123ft. by 35ft. The second floor will comprise the following rooms:—Life classroom, adjoining the art masters' room; art lecture-room, 40ft. by 35ft.; and suite of art galleries, all provided with roof lights on the north side for the whole length, and measuring 123ft. by 33ft., with a clear height of 20ft. in the centre. The architects have been the late R. J. Johnson, F.S.A., and Mr. Frank W. Rich.

OXFORD.—Mr. T. G. Jackson, A.R.A., has made a report to the members of Convocation on the condition of the tower and spire of St. Mary's Church. The tower and spire, which date from the 14th century, were repaired and restored about 40 years ago by Mr. Buckler. The material employed was Taynton stone, which has gone to complete ruin in all exposed parts, while the masonry of the spire itself, which dates from the time of the Edwards, is still in good condition. But the ruin of our modern work is also in part due to a false economy in construction—that is, in the way in which the stone was cut and bedded. Among other parts it will be necessary, in Mr. Jackson's opinion, to replace the statues, which, though extensively patched, are still valuable as fine examples of 14th century English sculpture. The material Mr. Jackson recommends as most to be relied on (Portland stone not being suitable to a Gothic building) is the hardest beds of Clipsham. The cost of the repairs to the tower and pinnacles round the spire he estimates at £8,732, the erection and maintenance of the scaffolding alone costing

£800. Besides this, the repair of the nave, parapets, and pinnacles is estimated at an additional £1,200.

SALFORD.—At the last meeting of the town council, Alderman Dickens, chairman of the health committee, moved the approval of plans prepared by Mr. Corbett, the borough engineer, for the erection of two blocks of four-story artisans' dwellings in flats on ground bounded by Queen-street, Starkey-street, Rolla-street, and Collier-street, and that the town clerk be instructed to apply to the Local Government Board for sanction to borrow £10,000 for the erection of the houses. He stated that the plans had been copied in great measure from the designs adopted by the London County Council, it being thought desirable that they should begin with some buildings on that principle by way of experiment. One objection taken to the plans was that they included so many single rooms and so few double rooms, but the reason was to keep the rents down, as the intended tenants would not pay more than 2s. 4d. a week. The inspector of the Local Government Board had declared that the plans were the most admirable he had yet seen. In the course of a short discussion, strong opposition was offered to the plans, Mr. Harrison declaring that houses erected according to such plans would be more insanitary than those that were being pulled down. Ultimately the resolution was withdrawn, and a committee was appointed to confer with the health committee with a view to the improvement of the plans.

SOUTHWARK.—The Royal South London Ophthalmic Hospital, built from the designs of Mr. Keith D. Young, F.R.I.B.A., was opened by the Duke of York yesterday (Thursday). It is four stories in height, and is built of brickwork. It contains in the basement a waiting-room for outpatients. On the ground floor are two consulting rooms, each with bandage, ophthalmoscopic, and consulting room attached. There are also on this floor a dispensing room and secretary's and officials' room. On the first floor are the surgeon's and matron's apartment, and on the two floors above beds for patients, with kitchen, &c., on the top floor. The floors are made of iron and concrete, and the whole of the fittings are of teak wood, which is rendered non-inflammable. Ample provision is made in the event of an outbreak of fire. The building is entirely warmed by hot water and lighted by electricity. There is not in the building an angle or projecting ledge which could harbour dust or injure a blind or semi-blind patient. The external red facing bricks were supplied by Messrs. Lawrence, of Bracknell, the stocks by Messrs. Smead and Dean, of Sittingbourne, the moulded red bricks by Mr. J. Brown, of Braintree, and the glazed bricks (used internally, by Messrs. Joseph Cliff and Sons. The terracotta was specially modelled to the architect's design by Messrs. Edwards, of Ruabon. The roof is laid with Claridge's asphalt, and the fireproof floors are by Messrs. Lindsay and Co. of Paddington, and the lifts are by Messrs. Archibald Smith and Stevens. Mr. W. Downs was the general contractor.

WELBECK ABBEY.—The new private chapel at Welbeck Abbey, which has been constructed in part of a spacious apartment latterly known as the church library, and originally a riding school, has now been formally opened. The building, which is from the joint designs of the late Mr. John D. Sedding and his pupil and successor, Mr. H. Wilson, has been divided by a row of marble columns, supporting an alabaster cornice and entablature, into a nave of five bays and two aisles; and the seating is arranged on the conventual system, two rows of canopied stalls running east and west in the aisles. The altar-piece is a silver electrolyte from a plaster model depicting the Divine Message to the world.

At the Tudhoe works of the Weardale Iron Company new slabbing plant, the largest in the county, has just been put down. It has been designed by Mr. H. W. Hollis, the general manager, and has a productive capacity of 1,000 tons weekly.

The new Parish Institute in connection with Christ Church, West Green, was opened by the Princess Christian on Wednesday, Dec. 7. The building is of simple oblong form, and is designed to be somewhat in keeping with the church. It seats nearly 900 people. The architect is Mr. George H. Fellowes Prynn, F.R.I.B.A., of 6, Queen Anne's-gate, Westminster. Mr. S. Wood has acted as clerk of works.

Engineering Notes.

CABLE TRAMWAY FOR STREATHAM.—Major Hutchinson, of the Board of Trade, made his formal inspection on Friday of the new cable tramway from Kennington Park to Streatham Hill, and it will probably be opened next week. Mr. Colam is the engineer, and Messrs. Dick, Kerr, and Co. are the contractors. The engine-room, boiler-house, car sheds, and offices are placed at the top of Streatham Hill. The cable system is applied to the Brixton and Streatham line of tramways from Kennington Church to the terminus at Telford-avenue, Streatham, a distance of a little over three miles, the cars being driven from Kennington to the Bridges by horse traction as at present. The cars will be attached at Kennington to a specially-designed bogie car, which is provided with the arrangements for gripping the cable.

THE VYRWY WATER SUPPLY FOR LIVERPOOL.—At a meeting of the Liverpool Engineering Society held on Friday, Mr. G. F. Deacon, M.Inst.C.E., read a paper entitled "A Sketch of the Vyrwy Works." Mr. Johnson, president of the society, occupied the chair. Speaking of the Vyrwy Lake, the lecturer said that the dam impounded the upper waters of the Vyrwy to a maximum depth in ordinary weather of 84ft. The contents of the lake were 12,131 million gallons from the level of the sill of the dam, about 825ft. above the sea, to the lowest level at which 40,000,000 gallons a day might be drawn for Liverpool. The lake was 4½ miles in length and from one-fourth to five-eighths of a mile in width. The area that naturally drained into it was 18,000 acres; but the Liverpool Corporation was empowered to take the water from two other streams—the Avon Conway and Marchant—which, when connected by tunnels with the lake, would increase the drainage area to more than 22,000 acres. The compensation water to be given to the river averaged 13,500,000 gallons a day. In addition to this 13½ millions, the lake would provide not less than 40 millions for the use of Liverpool in the most prolonged droughts. The first 18 miles of the Vyrwy aqueduct passed over mountainous country, the hills being tunnelled where necessary. From Oswestry for about 20 miles the line was kept as near as possible to the comparatively high land near the watershed between the Severn and the Dee. It then crossed the rivers Weaver and Mersey, and terminated at the Prescott Reservoir, nine miles from Liverpool. The total distance along the line of aqueduct from Lake Vyrwy to the Liverpool Town-hall was 77 miles. To Prescott the length was 68 miles. The only work involving very serious difficulty and danger in the undertaking was the construction of an aqueduct under the River Mersey. As finally carried out, the tunnel was unique in respect of the combination of its depth below the river, with the nature of the material passed through, which was heterogeneous in the last degree, and was perfectly loose.

CHIPS.

At a dinner given to his employes last week, Mr. C. Brightman, builder, of Watford, was presented by the men with a marble timepiece as a token of esteem. About 100 sat down to dinner.

Interesting discoveries have been made by Prof. Botts, who, while excavating in the neighbourhood of Pompey's Pillar, found a number of sarcophagi in the catacombs, and also remains of Christian dwellings.

Colonel Ducat, one of the Local Government Board inspectors, held an inquiry at the council house, Birmingham, on Friday in respect of an application by the city council for sanction to borrow £9,737 for the provision of branch libraries; £5,500 for the cleansing of the River Tame and the payment of certain law costs; and £4,500 for the purchase of water rights, and the settlement of a claim of the Warwick and Birmingham Canal Company. Mr. E. O. Smith, town clerk, explained the proposals.

Mr. Nicholas Joyce, A.R.I.B.A., of Stafford, has been appointed a surveyor under the Ecclesiastical Dilapidations Act, 1871, for the diocese of Lichfield. The appointment is for a period of five years, dating from Jan. 1, 1893.

The memorial at Kidderminster to the late Dr. T. L. Claughton, successively Bishop of Rochester and St. Alban's, will take the form of a chancel screen in the old parish church, designed by Sir Arthur Blomfield, A.R.A.

COMPETITIONS.

CROMPTON LOCAL BOARD OFFICES.—Fifty-two sets of designs were received by the Crompton local board in an open competition for designs for new board offices. The first premium has been awarded to Mr. H. Cheetham, Oldham; the second to Messrs. Woodhouse and Willoughby, Manchester and Stockport; the third to Mr. John Johnson, A.R.I.B.A., Victoria-street, London. Mr. John Wild, architect, Oldham, acted as assessor.

LONDON BOARD SCHOOL AT BROMLEY.—At the last meeting of the London School Board, the works committee submitted a report on the conditions for the competition proposed to be instituted for a school to be built in Priory-road, Bromley. The committee propose to adopt the R.I.B.A. suggestions for the competition, omitting, however, *b* and *c* of section 5, and sections 10 and 11. An assessor (the President of the Institute for the time being, or such person as he may nominate) will be appointed to advise the committee, and draw up the terms and conditions. The competition is to be for a school for 800 children, showing means of enlargement to accommodate 1,200 and 1,600 children, with all necessary class-rooms, staircases, cloak-rooms, and lavatories, and three halls; also alternative plans showing arrangement of one hall for the three departments, subject to, and in conformity with, the rules and regulations of the Education Department. The designs are to be accompanied by general specifications and reports showing system to be recommended for heating, ventilation, and drainage; also estimate of probable cost. Three premiums of £150, £100, and £50 will be awarded in the discretion of the assessor, and the whole of the plans will be publicly exhibited after the assessor shall have made his award, and before the same shall have been opened. The committee further stated that it is proposed to place in the hands of each competing architect a copy of the standard specification which was prepared by Mr. Ewan Christian and Mr. Rickman (who acted as professional advisers to the special committee in 1888); it being understood, however, that each architect will be at liberty to adapt it to his own requirements, he being held solely responsible for the drafting of the specification. Further, that if a set of plans be adopted by the Board, it is proposed that the architect should be paid the usual professional commission of 5 per cent. on the cost of the building; and that the work should be carried out entirely under the direction of the architect selected, and not under the superintendence of the architect or assistant architect of the board, and that a clerk of works to supervise the carrying out of the work will be appointed, and paid direct by the Board. The committee also reported that, in addition to the premiums proposed to be awarded, an expenditure, which will probably not exceed £200, will be required for the payment of the assessor who may be appointed to advise the committee upon the competitive designs, and for other expenses.

WALSALL.—We hear that the mottoes which have received the approval of the assessor for the Town Hall at Walsall are stated to be—1st, "Bruin"; 2nd, "Straight and True"; 3rd, "W."

WALTHAMSTOW.—We understand Mr. Wm. Landless, architect, Leeds, has been appointed assessor in a limited competition for an industrial school at Walthamstow.

The local board of Rugeley have decided to apply to the Local Government Board for sanction to borrow the sum of £5,750 for constructing works of water supply, from plans prepared by Mr. W. H. Radford, under whose directions the preliminary borings for water have been made.

Good progress is being made with the tower at Wembley Park, which is to be of steel throughout, the total height of the metalwork being 1,150ft. set on a base 162ft. in height. The firm commissioned to construct the tower is that of Messrs. Heenan and Froude, of Manchester, and the contract for the steel required in the construction has been placed with the Stockton Malleable Iron Company, Limited, Stockton-on-Tees.

A meeting of the Architectural Section of the Glasgow Philosophical Society was held on Monday night, Mr. Campbell Douglas, F.R.I.B.A., president, in the chair, at which Mr. J. Lindsay Miller, secretary of the section, gave a paper entitled "Notes on our Cathedral," dealing with the subject historically and architecturally.

Correspondence.

WESTMINSTER ABBEY.

To the Editor of the BUILDING NEWS.

SIR,—I was glad to see in your last number an illustration of the north transept of Westminster Abbey, as it offers a subject for special study to the student. To my mind, this transept façade is the best specimen of Gothic in England. It is more stately, has more elements of interest, more variety of detail than any other. The finely-recessed doorways, the arches in front of windows, the arcade above them, the double flight of buttresses are all notable features. Large churches in England are lamentably deficient in height and miserably inferior in the size of their doorways compared with French examples. Westminster Abbey Church is remarkable in that, though in detail it is thoroughly English, yet was designed under French influence, for in respect of height and importance of the entrances it is superior to any other English church, though not to be compared with those abroad. Possibly the original west doorways were superior to those of transept, features we might have gloried in, had not the Wren been robbing us. I should be heartily glad to see Wren's towers put into Mr. Pearson's hands for rectification.

There is another particular in which a marked difference exists between English and French churches. All the French cathedrals have rows of chapels down the aisles. Now there is no example of this in England. This is a remarkable distinction, and it seems to me to show our independence of thought and relative freedom from superstition, though pictorially our buildings suffer. It seems to be, however, a fact that superstition in this *fin de siècle* is growing upon us, and an illustration of objectionable Mariolatry is shown in this transept doorway, in the big figure of the woman and child. If the church had been dedicated to "Notre Dame," there might be some excuse for it; but the saint honoured is St. Peter, and it is the old fisherman and fisher-of-men that ought appropriately to stand on the centre pedestal. I was not sorry that the sceptre of the make-believe queen was broken off as soon as the figure was set up. Works of art to be respected must be respectable.

Though the effect of these doorways is good, they might be greatly improved by the addition of steps: there is but one now. If the pathway across St. Margaret's churchyard was made level instead of, as now, sloping, five or six additional steps could be got. Steps give great dignity. The splendid portals of Amiens would assuredly lose much of their effect without the steps by which they are approached. Steps at the transept no doubt did originally exist,—they are now at south aisle door—but the increment from burials in churchyard or in the levelling-up for the bridge have obliterated them north. Their restoration is a consummation devoutly to be wished.—I am, &c., M.

DRAINAGE AND PLUMBING SPECIFICATION.

SIR,—In view of the questions which might arise as to the reason why of many clauses in my specification which could not be explained in foot-notes, I have had it in my mind to offer some explanations as soon as the specification is completed.

I am indebted to Mr. Dicksee for his letter, as it is of great assistance to me in showing where further information is needed, and I should be obliged to him if he would continue his criticisms, either in the columns of your paper or privately. It is also very interesting to have these details discussed.

I am quite at one with Mr. Dicksee in his admiration for small pipes, although I think he carries it to an unreasonable and, possibly, dangerous extent, and fails to realise that a bright and well polished pipe is not the Alpha and Omega of the plumbing alphabet, as siphonage, the time in which it is required to empty baths and lavatories, the rules of vestries and other local authorities, which are often very unreasonable, and many other circumstances have to be considered.

I see that Clause 95 should have had a foot-note, explaining that the curved pipe would only be recognised when the soil or other pipe is in the same position in relation to the inspection-chamber as shown on Fig. 19, as is frequently

the case in London houses where there is no choice of position, either for the soil-pipe or the inspection-chamber.

Sometimes it is necessary to put the chamber even further up the drain. In such cases the pipe must have a greater curve than is shown on Fig. 19. I have found that if my channel bends (made by Messrs. Bolding and Son) are used, this plan will work well, and that the inspection-chamber and channel will be quite clean after long use.

I should prefer to postpone my reply to Mr. Dicksee's other criticisms until I see if more are offered, that I may deal with them altogether.

I am also indebted to Mr. Dicksee for exhibiting one of the main objects I have had in view in compiling this specification, which was to draw attention to the necessity for the greatest care in dealing with the details of plumbing work; and the more my work provokes criticism and inquiry, the more useful it will be; and while those who make use of it will be reminded of the different points to be considered, they will be able to vary the clauses either to suit their own ideas or the circumstances of the case with which they have to deal.

But in saying this I must add a caution against hasty judgment and untested theories.—I am, &c., ARTHUR BAKER.

ECHOES IN BUILDINGS.

SIR,—With reference to this matter, we may mention that in 1883 was applied to the Church of St. John the Evangelist, S.W., our "Eolus" waterspray system of ventilation, the result of which, with reference to this particular point, we quote from the *Builder*:—

"To the managers of theatres, and especially those of the lyric stage, good ventilation is also a matter of special importance, because it immensely improves the acoustic qualities of buildings. . . . A notable instance of this is the Church of St. John the Evangelist, Wilton-road, S.W. There, previously to its being ventilated, the preacher's words were almost indistinguishable to any but those who were in the immediate vicinity of the pulpit; but as soon as proper ventilators were fixed in the roof the echo disappeared, and the words of the preacher became audible throughout the church, from one extremity to the other."

The same question had also previously received considerable attention from foreign, and more especially, German scientists.—We are, &c., BAIRD, THOMPSON, AND CO., Ventilating Engineers.

165, Queen Victoria-street, E.C., Dec. 13.

DRAINING AND PLUMBING SPECIFICATIONS.

SIR,—Mr. Bernard Dicksee, in letter on the above, criticising Mr. Baker's specification, says that "no trap should be placed at outgo of sink or lavatory basin," and, further on, "the same applies to bath wastes." Perhaps Mr. B. D. will let your readers know what means he adopts to prevent current of air from R. W. head and waste pipe continuation (which in time gets foul) from passing up these open wastes direct into the building. Flap valves at outer end of pipe would partially prevent this in summer, and no doubt wholly in the winter, being sure to freeze and completely block end of pipe when the frost is at all severe. Plugs are all very well, but will be found to be generally left out until it is required to use the lavatory or bath.—I am, &c., F. S. I.

The summons against the London School Board for failing to comply with notices by the Lambeth Vestry, ordering certain sanitary works to be done at the Johanna-street schools, came on for further hearing on Wednesday at the Southwark police-court. The magistrate said he should order the board to pay five guineas costs, but the work demanded by the vestry having been done, he should make no order on the matter.

Mr. Acland received on Wednesday a deputation from the Metropolitan Vestries, the National Sunday League, and the Sunday Society, who came to urge the desirability of opening museums and art galleries from two till ten o'clock on Sunday. In reply, Mr. Acland said the speeches he had heard showed the increasing volume of public opinion in favour of the course the deputation had advocated. He would lay the views of the deputation before his colleagues, and it appeared to him that they had said much in favour of Sunday opening.

Intercommunication.

QUESTIONS.

[10913].—**Graecostasis.**—Where situated is or was this building, and for what purpose used?—STUDENT.

[10914].—**Rolled Beam.**—Would any authority on "strength of materials" please work out for me the following: A rolled beam, fixed at both ends, is to carry with safety a weight of 10 tons equally distributed over its length, which is 20ft. Calculate the size of its section from the following formula—

$$W = \frac{cad}{l}$$

and once this section is obtained, prove its accuracy by finding the distributed weight from the same formula. This has puzzled me very much lately, and should, therefore, be glad to have it properly worked out.—SCOR.

REPLIES.

[10907].—**Deadening Sound.**—Slag-wool is the best material to use. You can find addresses of those who supply this in the Directory, and they will tell you prices and method of fixing. Ballast or sand would be of no use. You will find slag-wool cheapest in the end, because effectual.—C. F. M.

[10907].—**Deadening of Sound.**—All air-harbouring bodies are good non-conductors of sound, but the best of these is "silicate cotton," manufactured from blast furnace slag. This indestructible glassy fibre is not only sound-proof, but fire-proof, and also antiseptic. It is largely used, and can be easily placed on the sound boarding.—M. H.

[10937].—**Deadening Sound.**—Nail strips to side of joists and board with rough pieces. Then put slag-wool or other like material on these boards to a thickness of 2in. or 3in., or more. Sometimes I have used mortar and chopped hay in the country, and with success.—G. H. G.

[10909].—**Orientation of Churches.**—Although it has been the most usual custom for Christians to pray towards the east, which accounts for the general ritual observance, there are many churches which do not orientate. In the basilican churches of Sta. Maria Maggiore, Sta. Cecilia, S. Giovanni Lalerano, and others in Rome, the altars are placed at the west end. In this country I may refer to SS. Mary and Nicolas, Wilton, Wiltshire, which church is built west and east, to St. Mary, Astbury, Cheshire, and many others, which do not observe the rule. One or two of our abbey churches are built north and south, but I do not remember which they are. In these cases the site has determined the position of the main axis.—G. H. G.

[10909].—**Orientation of Churches.**—St. Dunstan's-in-the-West, near Chancery-lane, and just inside the site of Temple Bar, has the altar to the north. Perhaps the chance is only a poor recess. St. Bartholomew the Great is all channel, as the nave forms the churchyard approach. Here the number of degrees towards north would be worth ascertaining.—H. W.

[10911].—**Light.**—Where a dominant owner has obtained an indefeasible right to a light by prescription, he cannot be interfered with. He is not only entitled to sufficient light for the due exercise of his business, but also to the greatest amount of light he can obtain, and the angle of 45 degrees is not a legal limitation, but is usually taken as an approximate limit of the new buildings. See "Yates v. Jack" (L.R. 1, ch. 295, 1886), and "Theid v. Debenham"—R. J. ANGEL, Birkenhead.

[10911].—**Light.**—In point of law, the courts have rather considered the substantial deprivation of light to an ancient window than any angle of 45 degrees, and I should be inclined to erect an experimental hoarding allowing that angle, and obtain the adjoining neighbours' sanction. In the case of "Parker v. First Avenue Hotel Company," Lord Justice Cotton reversed the decision of Justice North, who qualified the injunction allowing a roof at an angle of 45 degrees. In another case the Court ruled that the rule of 45 degrees was an element in the case, but a very small one, and no rule of law. Material damage must be shown to be caused. Notwithstanding these opinions, "J. W." will be safe in not exceeding that limit of height, but rather keeping within it.—G. H. G.

A workman's institute is about to be provided for Middlewick, on a site at present occupied by stables adjoining Naylor House. The plans have been prepared by Mr. R. T. Worth, surveyor to the Middlewick local board, and Mr. James Greenwood is the contractor.

Although not more than a third of the £20,000 required to carry out Mr. J. L. Pearson's plan for the restoration of Bristol Cathedral has been raised, there is a prospect of the work being shortly commenced. The proposal is to first take in hand the central tower and Lady chapel, the renovation of which is estimated to cost £6,500, and while that is in progress to make further appeal for funds, so that as soon as the first portion of the work is completed another section may be entered upon without delay.

For several months past St. Thomas's Church, Penkull, has been closed to permit of an enlargement. At a cost of upwards of £1,600 two new aisles and baptistery have been erected, the gallery has been removed to the south transept and a choir vestry constructed beneath it, and the whole church has been re-floored and re-seated. Additional accommodation has been provided for 166 worshippers. The church was reopened on Saturday, when the new baptistery, aisles, and other additions were dedicated by the Bishop of Shrewsbury.

Legal.

MORTGAGE OF BUILDING AGREEMENT.

A VERY important practical point has just been raised, and, so far, decided, in the case of "Church v. Sage—Froy, claimant" (*Times*, December 4), before Mr. Justice Wright, though it may possibly go up to the Court of Appeal. Sage, the debtor, had entered into a building agreement with a landowner to erect a house and take a lease. Being in want of money to complete the work, he assigned, by way of mortgage, to Froy all his interest in this agreement, and also all the plant and materials then on the land or to be brought in after, as security for repayment of a loan. There was no express power of seizure or sale in default of repayment. But there was an express guarantee to take possession of the premises, and of all plant and material, in the event of Sage not completing according to his agreement with the landowner, or in the event of his bankruptcy, or for other similar causes. The plaintiff had seized plant and material on the ground, which Froy now claimed under his mortgage, but which the execution creditor resisted, on the ground that this mortgage was a bill of sale, and so was void for not being registered. Thus the case came on as an interpleader, to decide the validity of this very ordinary form of mortgage.

It has, of course, long been settled that an ordinary agreement between a landowner and a builder is not a bill of sale, because of the contract it contains under which the chattels vest absolutely in the owner as part of the land, and so cease at once to belong to the builder. But in this case the document was a mere mortgage by a builder of his interest in the agreement to a stranger, to enable the builder to carry out his work, and so was subject to the usual incidents of a mortgage. The Judge held that "Reeves v. Barlow," and similar cases, only applied to building agreements and not to mortgages of this kind, which was, in fact, avowedly given as security for the repayment of money. Apart from direct authority, such a document would certainly seem to come clearly within the Bills of Sale Act. In the later case of "Climpson v. Coles" (1889, L.R. 23, Q.B.D. 465) there was a mortgage, and the Court seemed to think the same rule as governed agreements would apply. But there the mortgagor was himself the owner of the land, and the plant and materials were to attach to the fee simple as soon as they were brought upon the ground. In this present case there was nothing of that sort, and the assignment being given by the builder over chattels to secure repayment of money, it came within the Bills of Sale Act, and so was void for registration, and, therefore, judgment was given for the execution creditor, with costs. As it stands, this decision may have serious effects upon this common form of arrangement by builders wanting loans.

FRED. WETHERFIELD, Solicitor.

1, Gresham Buildings, Guildhall, E.C.

NOTE.—All questions for reply in this column must be headed "BUILDING NEWS," and must reach my offices, as above, by *Tuesday* morning to insure answer same week.

LEGAL INTELLIGENCE.

SCHOOL BOARD ACTION.—In February last W. H. Lorden and Son, builders and contractors, of Trinity-road, Upper Tooting, S.W., brought an action against the School Board for London for the sum of £460 5s., being the balance of 75 per cent. of an account of £1,413 13s. 4d. (£600 having been previously paid, leaving a total net balance of £813 13s. 4d.) for alterations to a house in Battersea Park-road, in forming new entrance, drainage, &c., to the Latchmere schools, which was, by the consent of the parties, referred to arbitration. The President of the Royal Institute of British Architects, appointed Mr. Charles Barry as arbitrator, who, after nine meetings at the Surveyors' Institute (in which Mr. Pollard appeared for the plaintiffs and Mr. Boyle for the defendants) and one meeting on the site, gave his award on Nov. 29th, as follows:—As to the plaintiffs' claim for £460 5s., being the balance of 75 per cent. of the value of the work done and materials supplied, subsequently, by the consent of the parties, increased to £813 13s. 4d., being the full amount of the balance claimed to be due in respect of said work done and materials supplied. I award and adjudge that the defendants do pay to the plaintiffs the sum of £745. And as

to the defendants' claim for compensation for delay, I further award and adjudge that the defendants have no claim or demand against the plaintiffs with respect thereto. And I further award and adjudge that there are no matters in difference in reference to the said works between the parties other than those with which I have herein before dealt. And I further award and direct that the defendants do pay to the plaintiffs their costs of and incidental to the reference and the costs of the award, and that defendants do bear their own costs of the same.

THE LEGALITY OF MASTER CARVERS TO CHARGE FOR STEAM POWER.—At the Clerkenwell County-court, on Friday, before Judge Eddis, George Saunders, wood carver, Central-street, City-road, sued Frederick Henry Ayres, master wood carver, of 111, Aldersgate-street, E.C., for £1 2s. wages due. Mr. Corry Grant, for plaintiff, said that in September plaintiff was in Mr. Ayres' employment as wood carver. It was the custom of defendant to deduct a certain amount from his men's wages every week for the use of steam power, and for the week ending October 3, 4s. 1d. was deducted from plaintiff's earnings. Plaintiff asked for his full money, 22s., and this demand being refused, the present action was commenced. Counsel had been instructed by the Cabinet Makers' Union, who had taken the matter up, they thinking that the question as to the legal right of masters in charging for steam power should be decided. The present action was a test case, and the Union were prepared to carry the matter, if necessary, to the House of Lords. His contention was that the masters had no right to make deductions from their men's wages, as the Truck Act prohibited any deductions being made unless a special agreement was entered into between the employer on one hand and the employed on the other. Plaintiff was called, and confirmed the opening statement. Cross-examined: He had been in defendant's employment for 18 months. He objected to the deductions because he was charged for steam power in an afternoon he had not worked. He was working on piecework. Re-examined: The best firms in the trade made no deduction for steam-power. For the defence, Mr. Dale contended that his client had not been guilty of any infringement of the Truck Act. James Mansell, defendant's foreman, and defendant's son having stated that plaintiff had not previously objected to the deductions, his Honour adjourned the case in order that he might look into the Acts of Parliament before giving a decision.

THE DISTRICT SURVEYOR AND HIS DEPUTY.—At the Lambeth Police-court, on Friday, Mr. H. A. Brown, a builder, of Herne-hill, was summoned by Mr. J. A. Woodward, district surveyor, for having proceeded with the erection of a building without having given notice, as required by the Building Act. The complainant said he discovered during the previous week that the defendant was erecting a dwelling-house at Herne-hill, without having first given the requisite notice.—Cross-examined: He was appointed to take charge of the Southern Lambeth District on Sept. 27, in consequence of the suspension of Mr. H. Parsons. He had not asked the defendant whether he had given notice to Mr. Parsons. He relied upon the list supplied to him by Mr. Parsons.—Defendant's solicitor called Mr. Henry Parsons, who said he received notice from the defendant, on Aug. 6 last, of his intention to erect some houses at the rear of Kestrel-avenue, Herne-hill. The notice was satisfactory to him as district surveyor. Mr. Woodward contended that, even if that were so, Mr. Brown was not entitled to proceed under a notice given as far back as August. Mr. Hopkins said this was a three-cornered fight between Mr. Parsons, the County Council, and the district surveyor. The summons must be discharged, with one guinea costs.

SERIOUS CHARGES AGAINST A BUILDER AND SOLICITOR.—At the Bow-street Police-court, on Monday, Henry Granville Wright, 50, solicitor, of Ordham Dene, St. Peter's-road, Croydon, and James William Hobbs, 49, managing director of J. W. Hobbs and Co. (Limited), of Norbury Hall, Streatham, were charged with forging and uttering a bill of exchange for £136 8s. 7d. Hobbs was also charged with stealing £29 9s., the moneys of J. W. Hobbs and Co. (Limited). Mr. Sims, for the Treasury, said that the accused were charged with forging and uttering a bill of exchange, and Hobbs was also charged with stealing a sum of money belonging to the Liberator Building Society. The accused had been arrested only on Sunday, and as there had been no time to get the witnesses, he proposed to give formal evidence of arrest, and ask for a remand. Henry Moore, inspector of the Criminal Investigation Department, New Scotland-yard, said he was present at the arrest of Hobbs at Norbury Hall, Streatham, his private residence, at nine o'clock on Sunday evening. Tonbridge read the warrant to him, and Hobbs said: "With respect to the two warrants for forgery I know I am entirely innocent. I have in my time signed hundreds of thousands of bills, many without signature of the drawer." With regard to the warrant for felony, he said: "I have for many

years past never touched a wages sheet, and for a very long time have never paid a penny of the wages myself." Wright, when charged at Bow-street, made no reply. The information on which the warrants had been granted were then read over. That of George Charles Kentish, formerly a cashier in the employ of W. Hobbs and Co., and now engaged in the liquidation of J. W. Hobbs and Co. (Limited), said that the business was turned into a company in 1885, with a capital of a quarter of a million. Before this Hobbs was financed by Wright and by the Liberator Building Society. He was indebted to Wright, and Wright was pressing for payment. It was arranged that he should be paid, and that to do this bills should be drawn and accepted by Hobbs, and presented for payment by Wright. The bills purported to be drawn by firms who supplied goods to Hobbs. They were drawn at one time to the number of eight or ten, representing about £2,400. Deponent was present when the bills were drawn, and knew that the proceeds were to go to Wright. The firm in whose names they were purported to be drawn had nothing to do with them. The names were left in blank when the bills were drawn, and were filled up by deponent with those of firms doing business. These bills were not entered in the ledger, and were not presented at the bank, but were paid by cheque by Hobbs. Wright's arrangement was that he was to have a cheque for them as they fell due. Hobbs was to get the money from the Liberator Building Society. A rough statement was drawn up by Hobbs for the advances to be made by the Liberator Building Society, and a cheque was drawn to meet this. The bills were not presented at the bank; but Wright was paid by a cheque or genuine bills. Hobbs signed these cheques, and they were payable to Wright, and not to the firm with the name on the bill. Wright was the solicitor to the Liberator Building society, and the moving spirit of all the companies. Deponent told Wright he thought it was a curious business. After the bills were all paid, Hobbs's business was turned into a limited liability company, and he was made managing director. It was the custom to draw cheques for the wages at the different jobs, and there were about 30 wages sheets got out every week. The cheques were drawn on an approximate estimate higher than the actual amount required, and that the surplus remaining after the men were paid went to Hobbs. Deponent admitted that he kept back a little for himself. Mr. Bailey discovered this, and spoke to deponent, who told him he was acting by Hobbs's direction. Deponent was transferred to other duties. He had received about £200 on the transaction, at the rate of about £5 per week. The deposition of Mr. Benjamin Bailey was to the effect that he had been secretary to J. W. Hobbs and Co. (Limited). It was Kentish's duty as cashier to check the wages sheets. It came to deponent's knowledge that they were falsified, and he spoke to Kentish, who told him it was done by the order of Hobbs. Deponent told him he must be dreaming, and informed Hobbs, who expressed his horror, and asked if anyone else knew of it. He mentioned another person, who was sent for, and Kentish was transferred. John Charles Watson, clerk to the Official Receiver, in his information, deposed that since the failure of J. W. Hobbs and Co. (Limited) in October last, he had been engaged in making an examination of the books. He found a bill (produced) purporting to be drawn by the firm W. E. Bradford and Co., and accepted by Hobbs, of which there was no trace in the books. He spoke to Kentish, who was assisting, with the result that Kentish gave him three other bills purporting to be signed by other firms, and subsequently made a full statement to the Treasury. Mr. Alfred George Blythe, in his information, said that up to December, 1893, he represented Messrs. George Wright and Co., who had dealings with Hobbs, but that a bill for £197 2s. 5d., purporting to be drawn by that firm, was not drawn by them, neither was there any record of such a transaction in their books. Mr. Vaughan remanded the accused till Friday, declining for the present to take bail, but expressing an opinion that there would be some further evidence required to connect the accused with the bills.

IN RE F. L. LINZELL.—Under the failure of Frank Lincoln Linzell, builder, Archway-road, a summary of the accounts has been issued, the gross liabilities being returned at £19,316, of which £4,497 are unsecured, with an estimated surplus in assets of £1,609. The debtor has been adjudged bankrupt.

IS A URINAL NECESSARILY A NUISANCE?—**GRAHAM V. THE CORPORATION OF NEWCASTLE.**—In the Court of Appeal, on Friday, Lords Justices Lindley, Bowen, and A. L. Smith gave judgment in dismissing the appeal of "Graham and Others v. the Mayor and Corporation of Newcastle-on-Tyne," from proceeding with the erection of a public urinal in Charlotte-square. The case was reported in our issue of July 29 (p. 164 ante), and commented on by Mr. Wetherfield in our issue of Sept. 30 (p. 479). It appeared that, by the original conveyances under which the plaintiffs claimed, each conveyance obtained an agreement by the

corporation that "the garden or open space" in the centre of the square "should for ever thereafter be kept open and unbuilt upon." It was admitted that this open space had not been used as a garden for many years. The plaintiffs moved for an injunction to restrain the corporation from proceeding with the construction of a urinal, on the ground that they constituted a breach of covenant, and that the urinal itself would create a "nuisance." Mr. Justice Kekewich held that the words "open" and "unbuilt upon" in the covenant were practically synonymous terms, and that the proposed building was not such a building as would interfere with the surface being kept open, and his lordship was not satisfied that the urinal would necessarily be a nuisance to the plaintiffs. He accordingly refused the motion. The plaintiffs appealed.—Lord Justice A. L. Smith delivered the judgment of the Court dismissing the appeal. He said that, by the indenture of February, 1886, all the Newcastle Corporation had covenanted to do was to keep the space in front of the houses open in respect of light and air. They were not bound to keep it for a garden. If the place erected was a nuisance, the plaintiffs must seek a remedy other than under the covenant. The appeal was dismissed with costs.

THE LONDON TRAMWAYS ARBITRATION.—An arbitration between the London County Council and the London Street Tramways Company respecting the purchase of four-and-a-quarter miles of the system, of which the lease expired in 1891, and which the Council decided to acquire under the 43rd section of the Tramways Act of 1870, was concluded on Friday before the arbitrator, Sir Frederick Bramwell, who throughout the six days' inquiry was assisted by Mr. Pipson Beale as assessor. It had been decided that rather than go to the courts on a case stated to raise the interpretation of the section in regard to the basis of value, the arbitrator should proceed to award; under a recent decision a case stated by an arbitrator could not be taken further than the Queen's Bench Division. The main difference between the litigants is as to whether the value is to be structural value or based on years' purchase of profits. Evidence was given by Mr. George Hopkins (consulting engineer to the company), Mr. A. Lance (Belfast Tramways), Mr. A. W. White (Portsmouth Tramways), Mr. Vigers (valuer), Mr. Garrod (surveyor), Mr. Lewis H. Isaacs (surveyor to the Holborn District Board of Works), and Mr. Glennie (the secretary of the company); and on behalf of the Council by Mr. A. Young (surveyor in chief), Mr. Herring (Birmingham Tramways), and Mr. J. Fell. The structural value of the four-and-a-quarter miles was given as £23,092, to which additions would have to be made for depots, cars, horses, and harness, which are to be valued by an independent person to be appointed by both parties.

BAD MORTAR.—On November 10, Messrs. Gill Bros., of the Minories, E., builders, appeared at the Thames Police-court in answer to several summonses taken out by Mr. Arthur Crow, district surveyor for Whitechapel, charging them with infringing the Metropolitan Building Act and the by-laws of the London County Council. The defendants are erecting several warehouses in the Minories and Haydon-hill. The district surveyor stated that on October 25 he found the defendants' mortar mill at work, and mortar being made from old brick rubbish without the addition of lime. He complained to the defendants, and served them with statutory notices to amend the irregular work. On October 28, he took a sample of the mortar in use on the building, which he submitted for analysis to Mr. W. C. Young, F.I.C., F.C.S., public analyst for Whitechapel, who gave evidence that the sample in question contained but 8 per cent. of free lime. At this point, upon a question as to the date of the offence being raised by defendants' counsel, the cases were adjourned. At the adjourned hearing on the 8th instant, the defendants, through their counsel, pleaded guilty to the offence, and Mr. Dickinson imposed fines amounting to £4 2s., and costs £2 6s., observing at the same time that these fines were to be taken as a "warning." Mr. F. W. Gill, who was summoned for a like offence in building the Horse and Leaping Bar, Whitechapel High-street, and who also pleaded guilty, was fined £2, and £2 2s. costs.

IN RE H. TOTEN, SONS, AND YOUNG.—The debtors, William Henry Toten, Thomas Toten, and Frank Broadfoot Young, against whom a receiving order was made on August 2 last, applied on Tuesday for an order of discharge. They had traded as builders in Gloucester-road, Kensington, and also in Fulham-road, under the style of H. Toten, Sons, and Young, and their liabilities were returned in the joint statement of affairs at £4,028; but proofs had been made by creditors for sums amounting to £4,768, and the Official Receiver certified that a dividend of 3s. in the pound had been paid. William H. Toten and Thomas Toten commenced business as builders in 1878 under the style of "Toten Brothers." About two years later their father joined them, and the name of the firm was changed to "H. Toten and Sons." Mr. H. Toten

died in 1887, and the business was continued by the two brothers under the same style until May, 1891, when they sought a partner. A balance-sheet of the firm was prepared, which showed a surplus of £5,488. On the faith of this balance-sheet the debtor Young, in May, 1891, joined the firm, bringing in a cash capital of £1,462, and the business was thenceforth continued under the style of "H. Toten, Sons, and Young" down to the date of the receiving order. It appeared to be now conceded that the balance-sheet in question was inaccurate, inasmuch as Thomas Toten had contracted in the name of the firm of H. Toten and Sons, a large debt which was not taken into account or disclosed in the balance-sheet or the books of the firm. The debtors agreed in attributing their insolvency to heavy losses on contracts occasioned by the strike of carpenters in 1891, and to losses by bad debts. W. H. Toten and Young alleged as further causes of the failure the liabilities contracted in the name of the firm without their knowledge, and the fact that moneys of the firm had been used by Thomas Toten without their sanction. The application was opposed by the Assistant Official Receiver on the ground of the insufficiency of the assets, and also of the book-keeping. He further submitted that Thomas Toten had continued to trade after knowing himself to be insolvent, and that he had also been guilty of gross misconduct amounting to fraud against his partners and against the creditors of the firm of Toten, Sons, and Young. Mr. Registrar Hope, in giving judgment, said he would grant an order of discharge to the debtors W. H. Toten and Young. With regard to T. Toten, he could not come to any other decision than that he had not only committed a fraud on his partners, but also on the creditors. Under all the circumstances he must refuse his discharge.

IN RE G. F. BENNETT, OF BIRMINGHAM.—A meeting of the creditors of George Frederick Bennett, builder and contractor, Bissell-street, Birmingham, was held on Friday. The gross liabilities are scheduled at £9,469 8s. 2d., of which a sum of £2,278 4s. 3d. is expected to rank. The net assets are £586 4s. 9d., leaving a deficiency of £1,691 19s. 6d. The Official Receiver observes that the debtor is the son of W. T. Bennett, who formerly traded as a builder at the same premises, 58, Bissell-street, and filed his petition on the 28th November, 1885, with liabilities amounting to £3,373 10s. 3d., and assets £476 4s. 3d. A dividend of 1d. per pound was paid. He applied for his discharge on the 6th May, 1886, when an order was made suspending it for seven years, which period expires on the 6th May, 1893. The debtor commenced trading immediately after his father's failure, having previously been engaged with him in the business. The insolvency is attributed to "loss on properties, losses in connection with the strike, and illness." The debtor was adjudicated bankrupt, and the public examination fixed for December 21.

IN RE J. B. LIVINGSTON, OF SCARBOROUGH.—The first meeting of the creditors of John Bishop Livingston, of No. 42, Aberdeen-walk, Scarborough, builder and contractor, was held on the 8th inst. The debtor's statement of affairs showed that his gross liabilities were £57,191 13s. 4d., of which £56,700 was secured, the estimated value of securities showing a surplus of £89 0s. 10d.; the unsecured debts were £483 0s. 6d. The assets were £760 4s. 10d., showing a surplus of £227. The Official Receiver said that the debtor had been a builder in Scarborough for 28 years. He commenced with £30. Apart from his building speculations the debtor considered that he was perfectly solvent. In November he was served with writs by mortgagees, and not being able to meet their claims, he filed his petition. The assets, in his opinion, were not over-estimated. The Official Receiver said the creditors would agree with him that the debtor's position was due entirely to his misfortunes, and not to rash trading. Several creditors concurred. The debtor was adjudicated a bankrupt.

The Building Committee of the Stamford Union met on Monday, and in the face of the large minority—18 to 19—which, at the meeting of the board on November 28, pronounced against the building of a new workhouse, decided to take no further steps in the matter, and to resign their appointment.

A Local Government Board inquiry into the application of the Southport Corporation to borrow £28,000 for works of electric supply was held on Monday at the Town Hall, Southport, by Colonel J. O. Hasted, R.E. The electrical engineer (Mr. G. Wilkinson), the gas engineer (Mr. J. Booth), and the borough engineer (Mr. W. Crabtree) were present. The works are to immediately provide for 1,900 lamps of 16c.p., and to be capable of supplying 6,600 such lamps. Street-lighting is not at present contemplated. The chief demand for some time will arise in the lighting of hotels, hospitals, shops, and private residences. No opposition was shown.

WATER SUPPLY AND SANITARY MATTERS.

LEIGHTON BUZZARD WATER SUPPLY.—An artesian-bored tube well, 144ft. in depth, has recently been drilled through the gault into the lower greensand formation, tapping powerful springs yielding a minimum supply of 290,000 gallons per day without materially affecting the head of water. Professor Atfield and Dr. Muter report the water as most remarkably pure. Messrs. C. Isler and Co., London, were the contractors.

ECCLESFIELD, NEAR SHEFFIELD.—A Local Government inquiry was held on Thursday at Greenside Workhouse, Sheffield, by Major-General Phipps Carey, R.E., one of the engineering inspectors of the Local Government Board, as to a scheme of main sewerage and sewage disposal for the town of Ecclesfield, for the Wortley Union rural sanitary authority. The scheme comprises main sewer pipes 18, 15, 12, and 9 inches in diameter, with complete ventilating and flushing arrangements, together with large tanks in duplicate, where the sewage will be thoroughly treated with Messrs. P. Spence and Son's aluminio-ferrie, which is suspended in a cage or iron basket immersed in the sewage to admit of the proper quantity being dissolved to effect precipitation. The clarified sewage is then passed on to land to be purchased from the Duke of Norfolk, laid out for intermittent filtration, with special under-drainage and ventilation; which, with regular and systematic management, will pass the effluent in a colourless and inodorous state into the adjoining stream. Mr. D. Balfour, M.Inst. C.E., F.G.S., of Newcastle-on-Tyne, explained the disposal scheme, and after hearing the evidence of others present (there being no opposition), the inspector visited the site, and will report in due course to the Local Government Board on the whole scheme, which is estimated to cost £7,000.

CHIPS.

Mr. Charles Henry Luard, Royal Engineers, one of the Local Government Board Inspectors, held an inquiry on Monday at the Town Hall, Sunderland, into applications by the Sunderland Town Council for leave to borrow £20,226 for the purchase of a site for a new lunatic asylum, for works of street-improvement, for laying out of the Roker Park Extension, and for alterations to the Borough Police-court buildings.

Mr. John Faed, R.S.A., the brother of Mr. Thomas Faed, R.A., has just presented to his native town of Kirkcudbright an interesting collection of paintings, mostly of a domestic kind, on condition that the town council provide a gallery for their exhibition. Mr. Faed is the son of an engineer, and exhibited his first works in Edinburgh over 40 years ago. He has lived in London for the last 30 years.

It is explained that the dissolution of partnership between J. Stiff, W. Stiff, and E. Stiff, trading under the name of James Stiff and Sons, London Pottery, Lambeth, S.E., announced on Saturday, is simply the formal notice of the retirement of Mr. James Stiff, which occurred in the year 1876, in accordance with the provisions of the partnership deed. The business has been, and will be, carried on under the same style by the two remaining partners, who have had the entire management for the last 20 years.

The premises of Mr. James A. Gordon, builder and contractor, of Newtownards, near Belfast, were totally destroyed by fire on Friday last. The loss is estimated at £1,300.

Mr. Philip D. Armour, of Chicago, has given £300,000 sterling to Chicago to found an Armour institute of science and art, modelled on the Drexel Institute at Philadelphia. The new buildings for the institute, which are situated in Armour-avenue, Chicago, are approaching completion.

A new school chapel, erected by the Independent Methodists in Bridgefields-street, Bury, Lancs., was opened on Wednesday week. The schoolroom is 48ft. 6in. by 32ft., exclusive of three classrooms, the largest of which is 22ft. by 9ft. 6in. In design the building is of the English Renaissance; it provides accommodation for over 600 scholars, and the cost, including furnishing and heating apparatus, is about £1,000. The work has been carried out from designs by Mr. J. L. Crumpleholme, architect, of Nelson and Bolton.

Reopening services in connection with the restoration of the Bourn Abbey Church were held last week. The restoration has been effected at a cost of £1,400. Mr. Traylen, Stamford, and Mr. Shilcock, Bourn, were the architects, and Mr. Roberts, Stamford, the contractor.

At the Walsall Police-court last week Joseph Ford, a local builder, was fined 30s. and costs in two cases—first, for omitting to provide damp-courses in nine double-fronted villas, and, secondly, for neglecting to deposit plans before commencing operations.

Our Office Table.

MR. ALFRED GILBERT, A.R.A., who has been advanced to the rank of Academician, in the stead of the late Mr. Thomas Woolner, is only thirty-eight years of age, and is the sculptor of the Jubilee Memorial of the Queen at Winchester, and of the Memorial to Earl Shaftesbury, now in course of erection in Piccadilly-circus. His monument of Professor Fawcett is in Westminster Abbey. He has in hand a new silver medal for the Architectural Association, and a bust of the late Duke of Clarence for the Queen. We gave his portrait and a biographical sketch on the same sheet with that of Mr. Woolner, his predecessor, in the BUILDING NEWS for May 30, 1890.

"REMBRANDT" was the subject of a lecture given at the Corporation Art Galleries, Glasgow, on Saturday evening, by Dr. J. Forbes White, of London. Lord Provost Bell presided, and there was a crowded attendance. The lecturer remarked that a successful artist must work with his hand, head, and heart—i.e., with technical skill, intellect, and deep sentiment. Rembrandt possessed all three in an eminent degree, but more especially the former and the latter, for his colour and form were sometimes disputed. Like Sir Walter Scott, he spent the latter part of his life in circumstances of pecuniary difficulty; but, unlike the Wizard of the North, the productions of Rembrandt's straitened days were his greatest. One very strong characteristic which Rembrandt impressed upon those who studied his pictures was that, although he frequently treated the same subject, his individuality and imaginative power were so intense that he never dealt with it twice from the same point of view nor in the same manner. Rembrandt brought etching to perfection—no advance had been made in that branch of art since his time. Dr. Forbes White congratulated the people of Glasgow on their possessing some good specimens of Rembrandt's skill.

A new theatre of some originality of plan has been erected in Brussels from the design of Mr. Jean Baes, of that city, and a folio volume, in illustration of the work, has just been issued by Mr. Lyon Claessen, under the title "Théâtre Flamand à Bruxelles." The main idea embodied in the arrangements for the safety of the public is the construction of external galleries or balconies on either side of the building at its several levels. The floors are of fireproof construction, and the theatre, being erected on an isolated site, has streets on all four sides. A very ample vestibule opens on to the grand staircases leading right and left, and over the entrance is a spacious refreshment saloon. Considerable space is devoted to a promenade at the rear of the boxes, and external to the auditorium. Several staircases reaching the various levels are placed along the flanks of the building, and to the rear are the artists' dressing-rooms. The building is sumptuously decorated.

AMONG the railway schemes to be brought before Parliament next session is the proposal for a Clapham Junction and Paddington subway, a revival on improved lines of a project brought forward in 1891. The proposal then failed, as it proposed to tunnel under Kensington Gardens a short distance below the surface; but the present scheme is for a subway 70ft. below the surface of the gardens. The fears of our correspondent, "Goth," that the quietude and beauty of the gardens would be spoiled by the line does not therefore seem to be justified by the facts. The route adopted is almost directly north and south, and a little over four miles in length. Beginning on the west side of Paddington Station, the first station is in Uxbridge-road, and the line is then carried by the side of the Serpentine in a straight line under Kensington Gardens to near the Albert Hall where there is a station, and then beneath Exhibition-road to South Kensington Station, and thence southwards beneath Sidney-place, and Manor-street, Chelsea, with stations in the Fulham-road, King's-road, and the Embankment. Burrowing beneath the Thames east of the Albert Suspension Bridge, the line passes on the west side of Battersea Park to Clapham Junction. The eight intermediate stations are conveniently placed, and the line, if sanctioned and constructed, would prove a useful and direct means of communication between the chief western and southern termini.

A REMARKABLE example of electrical transmission has been completed in Rome. The generating station is at Tivoli, 18 miles distant. Six turbines of 330 H.P. and three of 50 H.P. each are employed. The dynamos, of which there are three, each furnish a current of 42 amperes at a potential of 5,100 volts. These are connected "in parallel" to the line of four copper cables carried overhead upon oil insulators or iron poles. The current is said to reach Rome at a potential of 4,000 volts, reduced to 2,000 volts, and the total energy transmitted is stated to be 1,200 H.P. Apropos of electrical power, it is stated that the Columbian Exhibition will be lighted by 300,000 incandescent lamps.

THE Lord Mayor, as Master, and the Wardens and Court of the Plumbers' Company entertained at the Mansion House, on Wednesday evening, a numerous company. Sir W. Foster, M.P., Parliamentary Secretary to the Local Government Board, replied to the toast of "The Houses of Parliament," and congratulated the Plumbers' Company on having taken the lead in introducing a legislative measure the object of which was to improve the existing system of preserving the public health. That Bill, which had already been put before the House of Commons, was an exemplification of the wise action of the Plumbers' Company. The other toasts were: "The Public Health," proposed by Sir Joseph Savory, and responded to by Mr. T. Bryant, P.R.C.S.E.; "The Municipal Corporations of Great Britain and Ireland," proposed by the Lord Mayor, and responded to by the Lord Mayor of Dublin; "The Progress of Education," proposed by the Rev. Dr. Wace, and responded to by Capt. W. de W. Abney, C.B.; "The County Councils of the Kingdom," proposed by the Mayor of Birmingham, and responded to by Mr. E. Bayley; and "The Lord Mayor," proposed by Sir J. Crichton Browne, and responded to by his lordship.

THE annual meeting of the North of England district for the registration of plumbers will be held at the Literary and Philosophical Institute, Newcastle-on-Tyne, on Tuesday next. The mayor will preside, and Principal Garnett will give an address on "The Craft of Plumbing." The report of the council, which will be presented at the meeting, indicates that during the past year there has been a satisfactory amount of activity in two or three important branches of the work, more particularly as regards technical education. As a result of the special classes held at the Durham College of Science for the purpose of training a few selected men, classes have been established under the auspices of the Durham and Northumberland County Councils at several local centres. During the year 45 applications for registration have been considered, of which number ten master plumbers and nine journeymen were nominated for registration, the remainder being held over for further evidences of efficiency by examination. Several recommendations for the reorganisation of the district are made in the report, one proposal being that strong local committees should be formed at the large centres in the North of England district, each of which would appoint delegates to serve upon the Central Council in Newcastle.

AN Intercolonial Conference of Australasian surveyors has been held during October at the Custom House, Melbourne. The colonies represented were New South Wales, Victoria, Queensland, South Australia, Western Australia, and New Zealand. Mr. R. L. J. Ellery was elected chairman. A resolution affirming the desirability of a uniform system of examination for surveyors was carried, and the details of the scheme were discussed and agreed upon. In the evening of the first day's conference the members of the conference were entertained at dinner at the Freemasons' Hall, by the Victorian Institute of Surveyors. About 60 gentlemen were present, and the chair was taken by Mr. T. W. Fowler, President of the Institute. The toast of "The Representatives of the Other Colonies" was given by Mr. Stuart Murray and responded to by Mr. G. W. Goyder, of South Australia; Mr. A. C. Gregory, the veteran explorer and now Surveyor-General of Queensland; Mr. E. Twynam, New South Wales; and Mr. J. S. Brookling, Western Australia. "Success to the Conference" was proposed by Professor Kernot, and Mr. J. M. Coane gave the toast of "Our Visitors."

AN experiment in street-paving is about to be made in Glasgow with vitrified bricks in place of

the stone and wood hitherto used in this country for such purposes. Brick paving is common in some Continental towns, but the difficulty of procuring the right kind of material for the manufacture of bricks in this country of a sufficient hardness and toughness, has prevented that form of paving being fully tried for roadway purposes. The present experiments are to be made with an intractable material found on the estate of Lee, near Brandwood, and the bricks are to be manufactured by the Omoa Fireclay Company, who are erecting new works for the purpose. Whilst the material is called a clay, it is in reality an imperfect hematite ore, and requires to be quarried. A part of Buchanan-street, above Sauchiehall-street, leading to Buchanan-street Station, where the traffic is very heavy, is to be laid with the bricks, and also a part of Gordon-street, where the traffic is lighter. It is claimed for the brick blocks that they are durable, clean, healthful, easy to repair, and comparatively noiseless, while they are expected to be cheaper than either granite or wood paving.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Royal Institute of British Architects. "The Hypethral Temple," by Dr. William Dorfield, F.S.A., of Athens. 8 p.m.
Surveyors' Institution. 8 p.m.
Leeds and Yorkshire Architectural Society. Social evening. 8 p.m.
Surveyors' Institution. "Ventilation," by E. Tidman, F.S.I., M.S.A. 8 p.m.
TUESDAY.—Institution of Civil Engineers. Discussion on "The Manufacture of Small Arms." 8 p.m.

CHIPS.

The District of Shoreditch and the Liberty of Norton Folgate has been conferred on Mr. Henry Lovegrove, district surveyor of South Islington. It is a curious fact that the amalgamated district contains three vestry halls.

The new saloon of the Tyne Theatre, which has been designed and carried out under the supervision of Messrs. Oliver and Leeson, architects, of Newcastle-on-Tyne, has been opened this week. The work has been done by Mr. G. H. Moor, contractor; the electric lighting by R. J. Charleton, and the decoration by Messrs. Richardson and Son.

The Carlisle Town Council unanimously agreed on Tuesday to open out Lower-street to Eden Bridge, at a cost of about £10,000.

It has been proposed to erect a technical instruction school in Stamford. The site suggested is on the north side of the Shambles. Plans have already been prepared by Mr. Trayen, of Stamford. The building would have a frontage to Broad-street, and would comprise an upper room about 50ft. by 18ft. with movable partitions, and lighted to the north; while below there would be two rooms.

A new block of public washhouses, erected by the Edinburgh Corporation in South Gray's Close, High-street, were opened on Friday. They cost £3,450, and contain 26 washing-tubs, boilers, and drying-horses, a rotary wringer, and a suite of bathrooms.

The Leeds Art Gallery has received three additions of note during the past week. The original drawing of the town hall by Brodhill, its architect, has been purchased; a view of Cyffing Falls, Capel Curig, by John Peel, has been presented to the gallery, also the original etching of Kirkstall Abbey, executed by Axel Haig.

Mr. Percy E. Newberry, with a staff, consisting of Mr. Percy Buckman (artist), Mr. John E. Newberry (architect), and Mr. Howard Carter (draughtsman), left England this week for Upper Egypt to carry on the archaeological survey, under the auspices of the Egypt Exploration Fund. The capital of Tel-el-Amarna will be the main seat of operations for the season.

A new Roman Catholic church is in course of erection at Milltown, co. Kerry. It is Early English in style, will consist of nave, transept, chancel, and bell tower and spire. Mr. Daniel O'Connell, of Derrynane, is the architect, and the outlay will be £4,000.

The Goldsmiths' Company have offered to add £25,000 to the funds now being administered by the Guinness Trustees for the provision of dwellings for the poorer class of workmen, the chief conditions being that the sum shall be appropriated towards the cost of the block of buildings now approaching completion in Lever-street.

The Rev. S. O. Baker, of Much Elney, has restored to the Scottish regalia collection at Edinburgh the belt belonging to the sword of State for Scotland, given to James V. by Pope Julius II., and which had long been in private hands.

The Borough Surveyor of Widnes, Mr. John S. Sinclair, has been elected an associate member of the Institute of Civil Engineers.

Trade News.

WAGES MOVEMENTS.

KINGSTON-ON-THAMES.—Some time ago the master builders of Kingston-on-Thames intimated their willingness to concede the increased rate of wages—viz., 9½d. per hour—paid to bricklayers in the London district, and a strike was consequently averted. On Friday, however, it was announced that the Master Builders' Association, which has been formed since that time, intend to ignore the London rate, and pay only 9d. per hour. As a consequence, all bricklayers affected by the reduction have been called out.

AMALGAMATED SOCIETY OF CARPENTERS AND JOINERS.—Mr. F. Chandler, the general secretary, in this monthly report to the members of this society, reports that 41 new branches have been opened during the year, and that the recorded increase of members is over 2,000. New branches have just been formed at Brixton, Forest Gate, Aulsebrook, Marple, and Balth, besides two fresh ones in the United States.

CHIPS.

Worthing has declared in favour of the Public Libraries Act. A poll of the burgesses shows a majority of 739 in favour of its adoption.

At Monday's meeting of the Town Council of Harrogate a long discussion arose in reference to the new Montpelier Baths, and it was resolved that a special meeting be held to reconsider the question, with a view of modifying the scheme, and, if possible, selecting a different site for the baths.

A stained-glass window, the work of M. A. O. Hemming, of Margaret-street, W., was unveiled in the north aisle of Thornbury parish church last week. It contains four illustrations of the parable of the Good Samaritan.

Through the munificence of the new Dean of St. Asaph, that village-cathedral-city will shortly be presented with an ecclesiastical library and museum. The site selected and purchased is situated between the grammar school and the cathedral, and the erection of the structure proposed will proceed at once, contracts having been entered into.

The foundation-stone of a new church has been laid in Poynton Fen, near Billingborough, in the Fen district. The total cost of the building, including the internal fittings, will be about £300. It will be built of brick, from the designs of Mr. A. C. Wood, architect, Grantham, and the contract has been let to Messrs. Wadsley and Son, of Horbling.

The old market hall at Kendal has been refitted as a public library and newsroom at a cost of £2,500, raised by subscription. The reopening took place on Friday.

The Memorial Hospital, Mirfield, is now nearing completion. It is being warmed and ventilated throughout by Mr. E. H. Shorland, of Manchester. The large wards are warmed by means of Shorland's patent Manchester stoves with descending smoke flues, and the smaller wards by means of the patent Manchester grates. For the extraction of the vitiated air, Shorland's patent exhaust roof ventilators are used throughout the building.

In the application for discharge from bankruptcy made by Alexander Dorman, of Gunter-grove, Chelsea, builder and decorator, the discharge has been suspended for two years ending November 3, 1894.

The rebuilding of St. Mary Abbot's mission-hall and infant school, Kensington, for the Hon. the Rev. E. Carr Glynn, M.A., will shortly be undertaken. The infant school will be built according to the requirements of the Education Department, and the plans have been approved. The architect is Mr. T. Phillips Figgis, A.R.I.B.A.

Messrs. Potts and Sons, clock manufacturers, of Cookridge-street and Guildford-street, Leeds, have been chosen to supply the clock at Copt Hewick, near Ripon.

The sale of the first portion of Millbank Prison realised on Tuesday the small sum of £630. The buildings sold originally cost about £10,000 in materials alone.

The foundation stone of sub-central co-operative stores in High-street, Lincoln, were laid last week. The premises will be three floors in height, and will cover an area of 65ft. by 60ft. The chief elevation is Renaissance in character, and will be of stone. The cost will be about £5,000. The contractors are Messrs. Wright and Sons, the clerk of the works for the brickwork is Mr. C. Robinson, and for the woodwork Mr. Panton, the society's foreman joiner. The whole of the work has been designed by, and will be carried out under the supervision of, Mr. J. H. Cooper, architect, of Lincoln.

Mr. Gladstone's portrait, by John Macdure Hamilton, which was a feature of the Academy Exhibition of 1891, now figures in the Luxembourg Gallery, where the permanent exhibition of works by living artists has been reopened. Another of Mr. Gladstone's recent portraits, that by J. Colin Forbes, R.C.A., was presented on Monday to the National Liberal Club by Earl Rosebery, as the spokesman of the Liberals of Canada.

New board schools were opened on Tuesday week at Swatters Car, Middlesbrough. The schools have been built to accommodate 1,265 children at a cost of £10,000.

In our notice last week of the vacant curatorship at the Soane Museum, the late Mr. Wilde's Christian name was, by a printer's error, given as Joseph instead of James. The average number of visitors to the museum for the past three years has been over 3,300 during the six months it is open, in addition to 300 admitted by ticket during the remaining six months of each year.

A fragment of archaic Greek sculpture, dating c. 600 B.C., in white marble and of life size, of a man's head, has been presented to the British Museum by Mr. Webb, of Milford, West Surrey. It is perfect, except the nose, which has been broken away; and the chin has been repaired by some modern hand.

The names of Mr. John Anderson, slate merchant, Macduff, and James Christie, house carpenter, Banff, have been added to the commission of the peace for Banffshire.

Holloway's Pills never fail in correcting and strengthening the stomach, and in restoring a deranged liver to a wholesome condition, in rousing torpid kidneys to increase their secretion, and in re-establishing the natural healthy activity of the bowels. Holloway's are the remedies for complaints of all classes of society.

WALSALL TOWN HALL AND BATHS COMPETITIONS.

A PROGRESSIVE spirit has taken possession of Walsall, the busy Staffordshire centre of the tanning and harness-making industries, for it is astir with many municipal and sanitary projects. The Corporation of the borough invited architects to send in designs for a town hall, to be used for public meetings and other purposes, on an important central site of the town, lately cleared under an Improvement Act. The position is between three streets, Green-lane and Wolverhampton and Townsend streets. The site itself is of triangular shape, the obtuse angle being to the north, while the main corner, facing Park-street—the principal business street—is reserved for the chief entrance. The accommodation required, besides the main hall on ground floor, a basement for kitchens, dining-hall, lavatories, stores, &c.; on the ground floor, entrances for the orchestra, ladies' and gentlemen's cloak-rooms, lavatories, and retiring rooms, an orchestra and galleries round the large hall, having separate entrances, caretaker's apartments, with the necessary corridors and staircase communications.

Of the forty and upwards sets of plans submitted, three have been awarded premiums, these being "Bruin," by Mr. H. H. McConnal, of Walsall; "Straight and True," by Mr. H. A. Cheers, of Twickenham; and "W" in a circle, by Messrs. Malcolm Stark and Rountree, of Glasgow. The design of Mr. McConnal's is marked by some good features. The large hall, 95ft. by 51ft. 6in., exclusive of the orchestra, is placed with its axis parallel to Wolverhampton-street; the main entrance is at the Park-street corner, which is made an important architectural feature. The large hall is entered at this end as well as by side corridors, each 7ft. wide, which flank the hall, each of them having three entrances. The author has cleverly arranged his main entrance and lateral corridors. On the side towards Wolverhampton-street the corridor is terminated by projecting staircases, the one at the east corner forming the tower in connection with the principal vestibule, and the other the staircase exit from gallery and floor level. It is pierced by windows along the main front. On the north side of hall the corridor is architecturally united by a short corridor to the side entrance at the apex of triangle by the introduction of a circular vestibule, domed over as a lantern, and partially open to the corridors by columns. From this circular vestibule access is obtained to the mayor's parlour on one side of the entrance and to the gentlemen's and ladies' cloak-rooms on the other. The messengers' room and lavatories form triangular-shaped rooms on either side of this north entrance, the angular irregularity being thrown into the vestibule. Gallery staircases and exits are also provided at the ends of north corridor in connection with the great hall, and at the west corner at the back of orchestra there is an orchestra entrance and lobby, and two retiring-rooms. The first floor has a gallery all round the large hall. The town clerk is located in a room of hexagonal shape over the side entrance, or obtuse angle of plan; committee rooms are placed right and left over mayor's parlour and cloak-rooms, and the circular vestibule we have mentioned has a dome light in connection with north corridor, which gives

access to gallery. At the back of orchestra are retiring-rooms for the artistes; and over the principal entrance the upper part of vestibule is shown, with corridor connecting staircases on each side of the principal vestibule—a good point in this plan.

The author allows on ground floor of hall for 910 persons, in galleries 670, and in orchestra 230, making a total of 1,810.

In section the author shows a flat-pitched, iron-trussed roof over the hall, with large circular headed clerestory windows above the corridors, which project like aisles on each side; there are also the corridor windows. The interior features of hall include an elliptical arched platform end supported on pilasters, and some nice treatment of the side vestibule and entrances. The elevation towards Park-street has a semicircular entrance on steps, and over it a tetrastyle arrangement of pilasters supporting a pediment. Flanking this porticoed front on the south side is a tower of dignified proportion, plain and campanile-like below the main cornice, the upper story having a smaller square belfry, with disengaged angle columns in pairs, and cupola termination. The lower portion of tower is rusticated. The side elevation towards Wolverhampton-street shows circular-headed Italian windows, parapets and terminals at the angles.

The second design, by Mr. Henry A. Cheers, under motto "Straight and True," shows a similar general arrangement of hall, side corridors and entrances; but the author, carrying out the principle expressed in his motto, has made all the main walls and rooms straight and rectangular and balanced, and in this respect it differs from "Bruin." The triangular outline of buildings is broken by angles and cants, giving a rather more pleasing grouping to the plan. The hall, 100ft. 6in. by 56ft., has a circular ended apse for platform at the west end, round which and both sides the corridors traverse, though only one doorway to hall is shown in the centre of each side corridor besides the main entrance at the east end. The principal entrance is up a flight of steps to a rectangular hall, which leads into the large hall. This entrance hall is flanked by a tower which forms a gallery entrance, and is well proportioned, and has a pleasing outline. On the north side, conforming with the obtuse angle of site, is another entrance and grand staircase, on each side of which are the gentlemen's and ladies' retiring-rooms. The plan shows excellent provision for the artistes at the orchestra end, with separate entrance to stage and stairs to gallery; but there appears to be not so good an arrangement of entrances and exits as in the first plan. The author extends the seating area of his large hall by showing side galleries over the lower corridors, thus extending the width of hall to the outside walls, making it 75ft. wide. Piers divide the length of hall into six bays, and between these the width is 58ft. A deep gallery is shown over the end entrance hall, besides orchestra galleries on each side of platform at the other end. An organ recess is also shown. The shape of this end of the hall forms an octagonal recess, with quadrant-shaped corners, the irregular angle being filled with retiring rooms and staircase. The large hall has a curved flat inner ceiling over the centre portion, with flat ceilings over the galleries; it is well lighted by side windows in Wolverhampton-street, and over the roof of lower buildings on the north side. A centre ventilating trunk is shown on the section over the arched ceiling and a rather steep roof. The dining-hall is, as in other plans, in the basement, which looks rather ill-lighted by borrowed lights. The committee rooms are below the main entrance.

In external design, the Italian Renaissance is chosen, of red brick, with stone in the dressings. The main façade facing Wolver-

hampton-street has six semicircular windows with mullions and transoms; the arches are broken by projecting voussoirs, and the spandrels are filled with emblematic tablets and ornament with balustrades along the top. The gallery entrance porch has a semi-octagonal projection from corner tower; the platform roof is apsidal, and the large hall has a roof hipped at the ends. The main entrance-front is wanting in dignity; the gable end window and porch destroy the breadth of the design, the former being a little fussy in detail, but the redeeming feature is the tower. A coloured perspective is sent in.

"W" in a circle has some good points; the buildings are set out at right angles within the boundary lines, and present in plan a broken outline, well balanced. The main hall, as in the other two, runs parallel to the long side, with corridors on both sides, from a central hall at the principal entrance end. These corridors surround the platform end, which has a semioctagonal apse. On the north side, filling up the obtuse angle of site, is the dining-hall, forming a low-roofed building with domical lantern, and the roof of which building is on a level with the gallery of great hall. On each side of this triapsal-shaped dining-hall is a circular-ended staircase to gallery. The main hall has seating capacity for 968 persons. The circular-ended cloak-rooms on each side of corner entrance, and the stairs up to gallery and down to basement on each side of entrance vestibule, make a well-balanced front, which is pronounced by a boldly-designed round archway with massively-moulded piers and jambs. The lavatories and other necessary offices are in the basement. Three side entrances from each lateral corridor give access to the great hall. The section shows a flat coffered and coved ceiling, parapets, and a steep roof surmounted by a handsome flèche. The main elevation is broken by small gables over end windows; these are circular-headed and mullioned, with panels over, and the hall is pronounced, the ridge-line running through level, the whole having a dignity of character. The entrance elevation is broken by a curved and pinnacled gable, having a circular-headed window in the gable end, with large flanking terminal turrets at the corners. The drawings are rather rough and unfinished. A coloured perspective is sent in.

The authors of these designs have displayed much ingenuity in their plans; the shape and position of site have made it of importance to obtain at least three presentable fronts to the streets. Viewed from the east, the designs in some cases are rather chapel-like in character, not a few of them resembling the City Temple. The sum of £20,000 has been stated as a limit; but we have no reason to think that that sum will be greatly exceeded if the materials are of red brick and stone. The hall, which is to seat 1,800 persons, is rather small in orchestra accommodation in one or two instances, though additional room for instrumentalists and others might be improvised if necessary. The difficulty of making the obtuse angle architectural is obvious, as the buildings will be comparatively low and unimportant, and the oblique return lines will require some skill in bringing them into harmony with the two ends. No doubt on these grounds the rectangular treatment of the buildings, by breaking them to the boundary lines proposed by the two last premiated designs, and others of the unsuccessful, has the advantage.

In some of the returned designs this arrangement has been skilfully carried out, notably in the design under motto "Saddler's Arms." The obtuse angle is occupied by a low-roofed refreshment saloon or bar, that can be used in connection with the main hall, covered by a domical light, with a circular apse filling up the angle. Other good points in this design are the main central

tower entrance and gallery stairs, each being kept separate and having distinct entrances, and the quadrant lavatories, which are in connection with the cloakrooms on each side of vestibule, and which help to give variety and gradation to the return fronts. The value of making the side corridors available by swing doors for the purpose of entertainments in the hall is also exemplified in this and other plans.

The three designs for the public baths, now on view in the same Art Gallery, show a careful consideration of the conditions insisted by Mr. R. H. Middleton, Assoc. Mem. Inst. C.E., the borough surveyor, whose decision the council have wisely adopted. The site is an irregular one, bounded on two sides by a brook, and on the other sides by roads. The design placed first by that gentleman is by a London architect, Mr. Horace T. Bonner. Notwithstanding certain criticisms made by an anonymous correspondent some time ago, the author has in no way encroached on the land reserved by the corporation for houses and shops, which shows a clear depth from Lichfield-street of 75ft., except the centre passage way, 12ft. wide, to the entrances of baths. The author has the first-class and second-class swimming-baths placed with their ends to the brook and at right angles to Lichfield-street. The former is 80ft. by 30ft., with side dressing-boxes, and the second class 60ft. by 25ft. In front, and towards the entrance, are the Turkish bath and the men's first and second-class private baths; and on the right-hand irregular-shaped part of the site next the brook are, beginning at the rear, the ladies' and artists' rooms, a large washhouse, mangling-room, committee and engine-rooms, and in front, facing the street, the first and second-class women's baths and boiler-house. The entrances for men and women, with their halls and waiting-rooms, are well arranged, a waiting-room for each department being provided so that no confusion can occur. The pay-office is in the centre; on each side are the first and second-class halls for the respective classes, with corridors in direct connection therewith, so that the classes are separated; the first-class swimming-bath can be used for women or men, without interfering with other departments. Another good point is that the same distinction is provided for the Turkish baths, which occupy a square space between the two corridors and in front of the first swimming-bath. "Mermaid," the second plan selected, is, curiously enough, the work of the winner of the first design for the town hall. The swimming-baths are placed across the site parallel to Lichfield-street; the large one is 103ft. by 46ft., with a water surface of 85ft. by 30ft., and the second class is 76ft. by 37ft. out to out. The entrances are from the road from Lichfield-street. The ticket-office is in the centre, and corridors run between first and second-class slipper baths, these corridors look narrow. The plan is, however, well grouped: there is a gallery round the 1st class swimming-bath, the baths have elliptical iron roofs, with lantern lights, and the engine and boilers are well placed in the rear, and are accessible. The elevations are architecturally treated. The third design, "Health," by Mr. S. Loxton, shows the swimming-baths placed as in the first plan, with centre corridor and a cart road on south side. The entrances are not so well arranged, as the entrance for second-class men is so arranged that the men would have to pass by the women's second-class slipper baths. The Turkish baths are placed to the north of site; the women's and men's private baths are in front and side of the second-class swimming-bath. The roofs are also of the iron-tie class, and the elevations are simple but commonplace. The instructions provided that the first-class swimming-bath can be adapted as a gymnasium, and for this purpose the com-

petitors have provided a gallery round the bath in some cases. The total cost is not to exceed £7,000.

UNPROFESSIONAL PRACTICES.

IN the so-called "learned" professions there are certain rules of professional etiquette observed, especially in the law; any interference with the acknowledged rights and duties of one solicitor or barrister by another is sternly rebuked; but amongst architects there appears to be a very lax conduct in dealings with one another. A code of professional ethics has been often talked about, but no definite rules have been framed binding on the whole profession, albeit without this general agreement very little can be accomplished in this direction; in fact, we scarcely can hope to look for any such amelioration till the profession of architecture becomes a registered body amenable to statutory powers. There are many practices which daily take place among architects and surveyors which are certainly wanting in professional conduct, or that can be said to be decorous. One of the commonest customs is that of touting for work. In the provincial town especially the custom prevails to so large an extent that few people are inclined to take much notice of it. Mr. James Smith, a wealthy tradesman and town councillor, is about to build a residence, and as soon as the rumour is afloat he is besieged by several of the architects of the town, who are bent on the same errand of soliciting employment. Though it may be well known that the said Smith has consulted an architect who has even prepared designs, such information has no effect in the least on the canvassing proclivities of A., B., and C., who individually are eager to show their own superiority in professional skill, and even to vie with each other in detracting from the abilities of the other two, sometimes going so far as to blacken one another's character. Each sends a number of drawings of buildings, or goes so far as to prepare designs on approval, till Smith, wearied by these importunities, refuses to have any more interviews, or to see any more designs. We can understand a fair solicitation by sending a professional card when the contemplating building owner has not quite made up his mind; but the practice of "touting" after an architect has been engaged is most reprehensible and quite unprofessional. We know of all kinds of things having been said and done by touts of this class to win the confidence of clients as well as committees. We are well aware that in the excitement and rivalry of competitions some excuse may be found, but the most unwarrantable assertions are made, which in no other profession would be tolerated. A., B., and C. are competitors in the same town for a public building, whose designs are both well spoken of. A. obtains an interview with one or more of the committee or town council, and does not scruple to misrepresent B., or to pick holes in his plan; while C. goes so far as to print and circulate information to the detriment of the favoured design. We cannot find fault with the competitor who, when he has the opportunity, points out the merits of his own design and criticises the plans of others; but this sort of thing may become something worse than bad taste. When plans are under motto or number, individual criticism cannot do any harm, and must do some good in drawing attention to points of arrangement; but these disparaging remarks are often carried beyond the bounds of fair criticism. We protest certainly against the habit of some members of the profession who seek to prejudice the minds of committee and assessor while the plans are being discussed, and we think that such conduct is deserving of severe censure. After a decision has been made everyone has a right to say what he thinks of the design; it then becomes public

property. Architectural competition has indeed furnished many glaring examples of the need for a standard of professional ethics or conduct in matters of this kind. The most unparliamentary tactics have been resorted to, such as disclosing names, the private circulation of mottoes, correspondence in local papers, publication of private circulars, and other methods of influencing the minds of committees and the public. These are methods that ought to disqualify anyone who resorts to them. The practice of calling on members of committees in such cases is wanting in common respect and etiquette, and no individual who has any regard for his profession would condescend to do such a thing.

There are other practices which are equally culpable and unprofessional, and we notice a few of them here in the order they occur to us. It has been our unpleasant duty of late to record several instances of touting or advertising by so-called architects, in the remembrance of many readers. In those undignified announcements we often find the profession of architect associated with all kinds of trades and callings, such as those of builders, undertakers, auctioneers, house agents, and even public-house businesses. These advertisements are not only detrimental to their authors, but injurious to the profession, and cause it to be held in disrepute. The public at once draw inferences as to the status of those who thus tout, and unpleasant comparisons are made damaging to the profession. Quacks and mountebanks there always will be, but let the representative bodies of the profession try and stop a practice that has done incalculable harm to the calling.

A more reprehensible practice even than touting for business, because it involves the honourable conduct of architects, surveyors, and engineers, is that of interfering with or going between a brother architect and his client. We have known of cases where an architect or surveyor has been consulted or called in by a client who has disagreed with his own architect about granting certificates or the performance of work. We are not alluding to the case of a properly appointed arbitrator under the terms of a contract, but to an irregular invitation made by the client or the builder. In a properly drawn-up contract such an irregular interference would be impossible, as that of the following case. An architect declines to give a certificate of completion, whereupon the builder consults Mr. Bouncer, who writes a letter to the official architect asking for a meeting at the building to measure up and value the work executed. Of course the latter can decline to meet the builder's nominee who has the questionable taste to interfere with a brother architect's work. It is an unwritten law in the ethics of every profession that it is unprofessional and wrong to accept any consultation in a work or business in which another member of the profession is employed without invitation to do so from the latter. Yet we sometimes find an architect accepting an offer to pass an adverse opinion on his brother-professional's work, or even going out of his way to give advice prejudicial to the appointed architect. The effect of such criticism or advice is to imply a doubt as to the ability of the architect or engineer engaged without giving the latter an opportunity of explaining his mode of operation or of rebutting the advice. It is very easy to criticise. One may say, "I should have made the plan so and so," or point out a better or safer mode of construction of a roof than that adopted, without knowing the circumstances or the actual requirements with which the architect has had to comply. How often we hear of the architect's sanitary arrangements questioned by another of the same cloth—perhaps a trivial question of trapping or of ventilation magnified into an importance it scarcely deserves. The architect in charge has a right to be

first heard, and to accept or refuse the client's wish to call in an expert. If he refuses, the employer can only ask him to resign. No other course would be fair. The duty of the expert called in is clear: he should consult the architect before making any report.

A flagrant breach of professional etiquette is often noticed in the Courts of law. Professional witnesses are found really to give any evidence against their brother architect as to questions of fees or of negligence. This is the more glaring when their evidence is made to prejudice the jury, or by giving answers upon insufficient knowledge of the facts. Many other instances of unprofessional conduct might be cited if only we had the space; but those we have instanced are enough to show to what extent unprofessional dealings are carried on. An American contemporary has prepared a short code of ethics to meet these practices. The rules given are good as far as they go, but the difficulty in the way is the general acceptance of them by the profession as a body. The main societies and their affiliated branches should certainly use their influence to prevent these practices amongst their members. The rules of membership generally include restrictions as to certain kinds of practice; but our experience is that the transgressors in these instances of malpractices are not entirely confined to non-members of professional societies.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

AN ordinary meeting of the Institute was held on Monday evening, the President, Mr. J. MacVicar Anderson, in the chair. It was decided, on the recommendation of the council, to admit to alliance with the Institute the Institute of Architects of New South Wales.

THE HYPÆTHRAL TEMPLE.

A paper on this subject, written by Dr. WILLIAM DORPFELD, F.S.A., of Athens, and translated by Mr. Gill, was read by Professor Aitchison, A.R.A., Vice-President. Having summarised the violent disputes about the question of the existence and form of the hypæthral temples, and the diametrically opposed views thereon, as exemplified in the opinions of L. Ross and C. Bötticher, the author expressed his opinion that recent excavations had completely settled this point. Mr. F. C. Penrose's excavation of the Olympeion at Athens showed that this temple was octastyle, and thereby a new light was thrown upon the description of hypæthral temples given by Vitruvius (iii. 1). On this passage had been based the opinion that the Parthenon at Athens and the Temple of Zeus at Olympia were hypæthral temples, and from this it had been deduced that all the peripteral temples similar to these, with an interior order of columns, were hypæthral. By way of showing that this view is now untenable, the author proceeded, first, to note the chief arguments used for and against the existence of hypæthral temples. It was argued that the cellæ of many temples could not have received the necessary light from the door, and so a top light must be taken for granted—though opinions differed as to the shape of this opening: a wholly uncovered nave (K. F. Hermann); a small opening in the centre of the cella (C. Bötticher); openings of various shapes and sizes over the aisles (James Fergusson). To this argument he replied, that although the light entering through the door of a cella could not have lighted up the interior in the way necessary for a modern museum, yet such an amount of light was neither necessary nor aimed at. The impression produced by the statue would gain in proportion as its details would only gradually be perceived by those entering, after they had accustomed themselves to the semi-obscurity. In the similar case of the sculptures on the exterior of temples—for instance, the pediment and frieze of the Parthenon—no one had deduced from the fact of their elaborate details that they could not possibly have been placed so high up on the temple. That the illumination from the door was, moreover, not so small as people usually supposed, was shown by J. Durm's tabulated statement of the proportion of the door-openings to the area of the

cellæ of several Greek temples. To the argument from the existence of altars in the interiors of temples—that an hypæthron was needed for the escape of the smoke from sacrifices—it was answered that sacrificial altars were generally in front, and not in the interior, of temples; and that ceilings blackened by smoke were not considered unsightly. The author rejected the argument from certain finds which had been deemed to indicate the existence of a skylight in the roof of some temples: such as the curbstone found near the Temple of Ægina, and the tiles with round openings near the Temples of Olympia, Phigalia, Tegea, and Athens. These tiles were used for the lighting of the roof in those temples where the roof was accessible, and when it was not thought desirable to put a window in the pediment. We had, he urged, no certain bodily proof for the existence of an hypæthron in a Greek temple. Nor had the defenders of the hypæthral temple laid any great stress upon the arguments indicated above, but mainly based their theory upon a passage in Vitruvius, which had been shown by the excavation of the Olympeion at Athens to bear an interpretation totally opposed to the one that it had hitherto received. It was now demonstrated that the Olympeion was octastyle, and not decastyle as had been commonly held; and every reason for believing that the "octastylus" of Vitruvius was the Parthenon had disappeared. Neither Parthenon nor the Zeus temple at Olympia could now be named as hypæthral temples, nor could it be admitted that the majority of peripteral temples with an interior columniation were lighted hypæthrally. Those in favour of hypæthral temples had the onus of producing positive proof that the ordinary peripteral temples must have been lighted from above. He did not deny that the hypæthral temple did exist; but the temples which received their light through the ceiling were exceptions compared to the great number that were only lighted from the door. Dr. Dorpfeld closed by asserting that though a few great dipteral hypæthral temples existed, the Greek and Roman temples had as a rule no light from above, and were only lighted from the door.

Mr. F. C. PENROSE said he agreed with almost everything that Dr. Dorpfeld had advanced, but he did not think entire justice had been done to Fergusson's theory of the Parthenon. Mr. Penrose exhibited a restored elevation and plan of the Temple of Jupiter Olympeion at Athens as it was completed by the Emperor Hadrian after the Roman manner. He had found four short columns on the site, which were probably set up in the naos, and carried in Hadrian's time a coved and coffered inner roof. The statue of Jupiter, placed at the further end of the naos, was probably lighted through openings in the sloping sides of the pronaos, which could be closed when necessary to exclude the sunlight or rain. Such openings would not, he thought, be pressed through the ridge of the roof of the pronaos, and in so low a pitch of roof would not be apparent from without. The excavations had established the point that the Temple of Jupiter Olympeion was octastylar, not decastylar. He entirely concurred with Dr. Dorpfeld that the roof of this temple was never open throughout.

Dr. A. MURRAY, of the British Museum, said they all admired Dr. Dorpfeld, and recognised that he was apt to be thoroughgoing in his statements. He did not think that the roofs of the cellæ of temples were open, and from a passage in Vitruvius relating to the finding of the body of an armed man in the roof of a temple, it was evident that there was an inner and outer roof, and a considerable space between.

Mr. WYATT PAPWORTH pointed out that as the tiles of the temples were of marble and of large dimensions—3ft. 6in. by 2ft. 6in. at Bassæ, and 2ft. 6in. square at the Parthenon—it was possible that these were translucent, and afforded some dim light. There was a well-known tomb in the British Museum showing openings in the sides of roof.

Mr. MURRAY replied that the treatment of the tomb roof in question could hardly be taken as an illustration of hypæthral lighting. There were certainly small portions at one end covered in with panels, but these were probably only intended for the reception of offerings.

Mr. R. PHENE SPIERS said that in Egypt, where he spent five months, all the tombs were lighted only from the doors, and that in cases where the walls of absolutely dark passages were covered with paintings and sculpture that could only be

seen by artificial light. He had seen nothing in Greece to lead him to suppose that the temples were lighted otherwise than from the door.

Professor AITCHISON, in replying, referred to the difficulties experienced in ascertaining the meaning both of Pausanias and Vitruvius. There could be no doubt that in Hadrian's time the Temple of Jupiter Olympeion was lighted from above.

In reply to questions and remarks by Messrs. HUGH STANNUS, J. M. BRYDON, and W. KIDNER, Mr. PENROSE said there might be something in the theory that the marble tiles were semi-translucent, for all the examples of those tiles found were of the Parian marble, and not like the walls of the Parthenon of the closer-textured Pentelic marble.

ARCHITECTURAL ASSOCIATION.

THE fifth meeting of the present session was held on Friday evening, the President, Mr. H. O. Cresswell, in the chair. Attention was called by the President to the lectures in the Fourth Division of the History of Architecture. Few members had as yet sent in their names, and he requested those who proposed to join to write before the close of the year.

THE FORMAL GARDEN.

A paper on this subject, illustrated with numerous pen-and-ink sketches by the author, was read by Mr. F. INIGO THOMAS. In his introductory remarks he satirised the views propounded and methods adopted by the modern landscape gardener, contending that his work lacked definiteness and virility. Since the very origin of the word "garden" is garth, an inclosed space, my conception of a garden is, Mr. Thomas continued, a walled-in area, and among the characteristics of the formal garden you may safely put inclosure at the head of the list. No matter what the form of this boundary, each inclosure will be a separate garden in itself; hence the plural term "gardens," which, if applied to the work of the landscapist, has no meaning at all, since his scheme (if so it may be called) wanders on indefinitely, without let or hindrance, except for such weak bounding lines as are afforded by an iron railing three bars high, or a sunk fence. In the old engravings the garden-courts are sometimes figured with reference to a note, in which case we find them described individually by such terms as "west garden," "base-court," "parterre," "coronary garden," and the like; but the walls and hedges that were employed for this were not only of use in keeping distinct the various kinds of gardens. In 1701, we read in Defoe's "Tour," "The Pond-garden (at Hampton Court) was laid out into small inclosures surrounded by tall hedges to break the violence of the winds and render them proper for the reception of such exotics in summer as were moved out of the conservatories during the season"; and Mr. Baring Gould, in his book on "Old Country Life," comments on the capital shelter that these garden-courts afforded. For this purpose yew is certainly the next best thing to stone or brick, and in some respects even better. A wall is more monumental, but, if unsympathetically built, will never give a chance to all the wealth of vegetation that makes the charm of an old wall. Again, a wall is not so hostile to a flower-border as a yew hedge, for the yew, being a greedy plant, sucks much of the good from the surrounding soil that ought to go to the flowers. But against this, it may be said that there is no finer background for flowers than the sombre green tapestry of yew, and there is no better protection from wind than is to be obtained by the filtering property of a thick hedge. And besides the actual use these divisions are for shelter, they also have a sentimental charm in the idea of seclusion and mystery that they give to the ground so divided. I know of nothing more suggestive of hidden beauties, and more stimulating to the imagination, than a glimpse of sunlit lawn with stately flights of steps that is sometimes caught through an open garden door. Given the inclosure, in my ideal garden formality goes a little further. The paths are straight, or, at least, geometrical. The flower-borders inclosed with a trim edging of box, and the fountain has its softly-moulded rim of mossy stone. The turf is level as a table, and whatever standard yews are necessary to emphasise points in the design will be clipped into such quaint shapes as shall suit my fancy. But inside the borders and over the walls flowers and

creepers run riot. From the works of the landscapist, one would judge that, having made his borders irregular in outline, he feels that his responsibility is ended, as it seemed to be a matter of indifference to him whether they are planted with formal lines of flowers or not. The beds so planted in the London parks are of use to inform us how even in size certain plants can be grown if properly tended; but there the interest ends, and we begin to wonder whether after all the game is worth the candle. In short, the landscapist's garden is no garden at all, but merely a wilderness; and in bringing his wilderness close to the house he is not only reversing the time-honoured usage of our forefathers, but is acting contrary to what must appear to be reason to all those who value decency and order. His vaunted natural treatment of the ground is not natural, but only slovenly artifice, and I would go so far as to put forward the apparent paradox that it is most natural for man to be artificial. The history of the early gardens in England is a little enveloped in obscurity. In the old MSS. they appear to be referred to rather as fruit-orchards than flower-gardens. For example, in the office of the Duchy of Lancaster is preserved an account rendered by the bailiff of Henry de Laci, Earl of Lincoln (who died in 1312), of the profits arising from, and the expenditure upon, the earl's garden in Holborn, then in the suburbs of London, in the twenty-fourth year of Edward I. £9 2s. 3d. in money of that time—equal to about £135 of modern currency—was received in one year from the sale of fruit alone. This tends to show that profit was the main object with which the garden was kept up. Alexander Necham evidently had in his mind the idea of a garden for pleasure when he said that a "noble garden" should be arrayed with roses, lilies, sunflowers, violets, and poppies. But probably much ingenuity was not shown in the design of gardens until the 15th century, when fountains and conduits begin to grace the pages of illuminated manuscripts. We hear of an early garden at Westminster and another at Windsor, but at first the flowers seem to have been a secondary consideration to fruit and vegetables. It was the growing popularity of the game of bowls, requiring, as it does, a broad expanse of level turf, that paved the way to the great pleasures of a later date. As to whether terraced or hanging gardens existed here in early times we are left rather in the dark. Many people seem to suppose that this method of treating the ground was the direct result of Italian influence; but they are apt to be blind to the very essential differences between an Italian and an English garden. They ignore the preponderance of turf to gravel, the habit of growing more plants in beds than in tubs, the restraint in the matter of statuary, and the peculiarly English colouring that is given to the whole by our northern climate and materials. And even if, after all, we are bound to admit foreign initiative, why, pray, should we call our gardens Italian, if we feel our buildings at that time to be so essentially English that we have had to call them Elizabethan? The privy purse expenses of Henry VIII. give us a good deal of information with regard to his gardening operations. These, with the help of a contemporary picture or two, and some little imagination, may conjure up for us a fair idea of the Royal garden at that time. It appears to have been framed on a comparatively small scale, walled in and divided into four compartments by gravel paths, and the borders protected by barber-poled railings with a royal beast holding a flag at every corner. A part of it is to be seen through the doorway in a picture (by Holbein?) now at Hampton Court. The garden at Nonsuch was, perhaps, much in the same state as at the time of Henry VIII.'s death, when it was described by an eye-witness. All through the reign of Elizabeth her courtiers were vying with each other in the splendour of their palaces and gardens. John Thorpe shows a design for one among his drawings at the Soane Museum. He notes, by the way, that there is to be "nothing out of square." Hatfield, Longleat, Hardwicke, and all the grand buildings of that most stately period had similar surroundings. Their arrangement was, with infinite variation in detail, something as follows:—Between the projecting wings of the house on the entrance front a space was paved in stone or marble, with a few steps leading down to a gravelled court with walls on the side connected with the house. This was called the "forecourt," and often had a

fountain in the centre between the porch and entrance gateway, with garden doors on the other two sides, as you may see at Montacute, in Somerset. Before arriving at this court there was in many cases a sort of ante-court, which seems to have been for dignity solely. In those days it was not the custom for guests to alight at the front door. To one side of the house, and a little apart from it, stood the stables, with a kitchen-court between them and the house. This was called the base-court, and in it was hidden away all the untidiness that is consequent on the proximity of kitchen and stables. On the other sides of the house lay the more ornamental pleasure-gardens, under which head comes the "parterre," the bowling-green, the "coronary" garden, herb-garden, &c. Perhaps the best contemporary account of an Elizabethan garden given with any regard to detail is to be found in a letter written by one of the officers of the Court to Master Humphry Martin, mercer, of London. It is dated from Kenilworth, 1575, and describes a visit of Queen Elizabeth to the castle and, *inter alia*, the gardens. In front of the castle was a terrace walk raised 10ft. above the garden and 12ft. wide; at either end were arbours "redolent by sweet trees and flowers," and along the balustrade, on the garden side, obelisks, spires, and coats-of-arms in stone were set out at equal distances. Below this terrace was a garden, an acre or more in extent, divided into four quarters by fine sanded walks. In the centre of each plot rose an obelisk of red porphyry with a ball at the top. The garden was planted with apple trees, pears, and cherries. In the middle of the wall, opposite the plot, was a great aviary, 30ft. long, 14ft. broad, and 20ft. high, and in the centre of the garden a fountain of white marble rose out of an octagonal basin. John Evelyn, to whom we are indebted for much information on the subject, had always had it in his mind to write a great book on garden design; but, unfortunately for us, he never got further than the headings of the various chapters. Among these, however, are references to the stage properties of the garden grandeur of his time, quite enough to show how much of garden-lure has been entirely forgotten. Through the latter half of the 17th century garden design had been making great progress, though Charles I. had not done much to encourage it, leaning as he did rather to horticulture than design. Neither do we hear of a great deal being done under Charles II., though he it was who dug the canal at Hampton Court, and made the garden at St. James's. It is difficult to arrive at a very clear idea of the development of garden design up to the time of the Dutch influence, because it was not till then that engravings of country seats drawn from bird's-eye points of view became common. A Dutchman named Knyff was employed at the end of the 17th century to make surveys of many places in different parts of England. This he effected with marvellous accuracy, and handed over his drawings for engraving to a fellow-countryman, Jan Kyp, their joint efforts being published in a large folio, entitled "Britannia Illustrata." From this time forward it becomes an easy matter to trace the course of design. Kyp continued for some thirty years to engrave subjects of a similar kind for various publications, notably Harris's "History of Kent" and Atkyn's "Gloucestershire." After his death, in 1722, his mantle seems to have fallen upon John Harris, who engraved some of the drawings by Badeslade in "Thirty-six Views of Gentlemen's Seats in Kent." This Badeslade was an indifferent artist, as may be gathered from some drawings by him now at Mount Edgecumbe, showing the grounds there as they appeared in his time. In the diary of Celia Fiennes, a lady who rode through the country for her health in the days of William and Mary, recently brought to light from a lumber-room, we get a quaint description of the gardens at Epsom and elsewhere. If we are anxious to know what has happened to all the glorious gardens that she attempts to describe, we must consult the shades of "Capability" Brown, Repton, and the like. For all their vaunted worship of the beautiful, they were great sinners in this respect, and demolished every old garden that came in their way. Sir Uvedale Price, perhaps, if he had lived in our own day, would have been a devoted adherent of the formal school; but he was swept along by the tide of public opinion, and small heed was paid to his touching lament over the destruction of his own

garden, a mistake he realised when too late to remedy. The really grand schemes for approaches, avenues, and much more that lends dignity to a building were generally due to the architect. In 1699 Sir Christopher Wren made a grand scheme for alterations on the north side of Hampton Court. A plan of this exists in the Office of Works, and shows a great courtyard facing north, with a semicircular colonnade leading up to the centre of the banqueting-hall. From this entrance a vista of some miles in length was to lead northwards, flanked by avenues of trees, four rows deep, on either side. At a convenient distance from the palace a cross avenue is shown, and at the intersection a large circle, called the "Diana Circle," where now stands the great fountain in Bushey Park. These avenues are all that was ever carried out of a conception that would have made a truly magnificent approach to Hampton Court, which is, of all things, what the palace most requires. This scheme was on an altogether increased scale to that which was actually carried out on the east side. When Sir Christopher had framed the Churches of Hampton, Surbiton, and Ditton, so as to meet the eye standing in the central doorway of his eastern façade, he perhaps felt emboldened to attempt a still greater stroke on the north side. And Wren was working for a master who was likely to appreciate the extreme grandeur of his conceptions—King William, who passed much of his time at the Royal Palace of Loo, in Holland. Recollections of Loo, coupled with a hope long cherished by the King of rivaling the glories of Versailles, have made Hampton Court what it is, and it is a matter of regret that the loss of his patron prevented Sir Christopher from completing the whole of his contemplated designs. One is accustomed to be told that Harry Wise was the King's adviser in all these matters, but in reading the accounts of the alterations at Hampton Court during this reign, it is evident that the general conception originated in the mind of Sir Christopher, and it was only the details that were left to be carried out by Wise. The progress, which had continued under Wren, with the help of London and Wise, up to the death of William, was succeeded by a decline, gradual at first, but rapidly increasing through the reign of the Georges, till Addison's scoff and Pope's satirical verse sealed the fate of the English formal garden. However short of a healthy revival, nothing better could have occurred since design had fallen into the hands of the nurseryman, and the stately old gardens lost their charm, when the tender care was gone that had kept them trim and neat. Kent followed, and in the words of Walpole, "Leapt the fence, and saw that all nature was a garden." This meant that the old walls were pulled down, and so-called Nature allowed to usurp the place of the garden proper. "Capability" Brown next appeared on the scene. This man was allowed extraordinary licence, and no better example can be found of the tyranny of fashion over weak minds than is afforded by the history of gardens under his iron rule. He was the king of the landscape school, and certainly his ideas were not lacking in scale; but he had an innate horror of anything approaching dignity, which led him to cut down avenues and generally mutilate what had taken years of honest labour to effect. Cobham, in Kent, is an instance of his handiwork. Five avenues of limes once radiated from the central front, but four of these fell victims to his mania for destruction. He travelled about England, compiling books of suggestions for alteration of the various places. Coloured sketches of the house and surroundings as it appeared were covered with a fly-leaf, on which he drew his suggestions, the result being that English parks were enlarged by the addition of the gardens; but the English garden practically ceased to exist. And then, forsooth, we hear writers of the present day (on horticulture, be it observed, not on garden design) claiming the title of "English garden" for the anomalous production that has been in vogue from that time up to the present. "Capability Brown" had as followers in his train Repton and Sir Uvedale Price, who handed on the tradition, such as it was, to the Hughes's, Milners, and Robinsons of our own day. Mr. Milner, in a book distinguished neither as an effort in literature or the better qualities of etching, has retold the old story, already so well worn; and Mr. Robinson's publication stands a confessed counterblast to a book on the formal garden in England brought out by Mr. Blomfield and myself. To these three books I must refer

you to form an unprejudiced opinion on the subject. Having given you a slight sketch of the rise and fall of garden design in general, you will be anxious to hear something more of the details employed in the realisation of these efforts. Perhaps the principle that seems of most importance after that of inclosure is change of level, and a great deal of variety is to be obtained by close-shaven turf seen at different angles with the light. Whenever possible, it has always been preferred that the ground should fall from the house rather than towards it, and though, of course, instances of the former treatment are most usual, still there is a certain charm in the latter, too—which charm lies more in the view of the house from the garden than of the garden from the house. Tissington, in Derbyshire, and Kilworthy, near Tavistock, afford the peculiar effect that is hinted in Sir John Millais's picture of a garden with the gables and chimneys of an old Scotch manse just visible above the walls. The position chosen for the principal terrace was always, if possible, next to the house. But if, as at Rycott, near Thame, the house already lay low, and new gardens came to be added subsequently, rather than forego the terrace altogether it was raised in masonry at the far end of the garden, and in this case the space underneath formed an orangery. Packwood, in Warwickshire, has a terrace 3ft. high between the garden and orchard, with steps on either side, and at Hampstead Marshall there still remains an artificially-raised terrace of generous proportions. Nothing seems to have had such a stimulating effect on the imagination of garden designers as rapidly falling ground. Wherever there have been these conditions a grand chance has come with them for ingenious device in steps and gradients connecting the various levels. Terraces were sometimes carried round two or three sides of a garden if the fall of the ground suggested such a treatment. Penshurst, in Kent, has a long terrace down one side of the main garden, and a wide one next to the house. Cusworth, in Yorkshire, has raised walks round three sides of the bowling-green, and Oxenhoath, Kent, is shown in Badeslade's view with a terrace running round two sides of the garden next to the house, terminating in a pavilion. The more fall, within reason, from terrace to garden below, the better and bolder will the effect be. Haddon has a fall of 16ft.; Pitmidden, 13ft.; and Newton Ferrers, in Cornwall, 8ft. At Oxford, the walk on the ramparts forms a sort of terrace to those of the College gardens that lie under the city wall, such as Merton or New College, for example. Another form of earth-work that is to be found in some old gardens is the mount. This was made square or circular, with sloped sides and terrace walks at intervals, with a railed space at the top commanding a view of the country around. That in the garden of New College still exists; it is 40 paces square at the base, and about 30ft. high, and though now entirely covered with trees and undergrowth, among their roots may still be found the stones of the steps that led from terrace to terrace, and the curb that bordered the paths. This mount is engraved in a view of the gardens by Loggan in the seventeenth century. The largest mount that I remember having seen is at Heath Hall, Wakefield, and is locally called Mount Tarribyte, but it is on such a large scale that at first sight it is difficult to believe that it has formed a part of any garden scheme. Bowling-greens were generally square, though sometimes a circular instance is to be found, as at Knole, in Kent, where it was surrounded by tall hedges of hornbeam, with arbours on two sides, and a sort of baldaquin in clipped work over the steps that led down to the house. This green was forty paces across, and that at Bingham Melcomb, Somerset, thirty by thirty-four, from which it would appear that dimensions were optional. There is a curious oval-shaped bowling-green facing the house at Campsea Ashe, in Suffolk, twenty-five paces by fifty-two. A fine, old yew-hedge runs all round it, and from this rise at intervals twenty clipped yew-trees, with entrances on the four opposite sides. Grass alleys of ample width formed another pleasing feature in old gardens, and were bordered with clipped greenery or palisades of fruit-trees, throwing a broad, even shadow across the turf. Statuary in stone, lead, or bronze, played an important part in garden ornament. Obelisks, sundials, and heraldic beasts, with, perhaps, a curiously-wrought fountain or two, seemed to have formed the stock-in-trade of Elizabethan

gardens. Perhaps of all the features of old garden design, none has called forth such violent invective as the custom of pleaching. It is generally supposed that it came in with the Dutch influence, but inquiry proves that it was the custom in England from much earlier times than these. On the other hand, it was under the Dutch influence that it was carried to such excess as ultimately to bring the formal garden into disrepute from this very cause. No one who has tried it will deny that a yew-hedge when clipped gives a much quieter background for flowers than if left to its natural growth. Kings and queens carved in yew, or foxes jumping through a hoop, as you may see at Broome Hall, in Suffolk, hardly tend, however, to ennoble the whole effect of the garden. However, at Parkwood, in Warwickshire, there is an instance of pleaching that follows out a definite scheme through the whole garden, and commands more serious consideration. The main walks in this garden follow the shape of a capital T, and at the crossing rises a mount, with a tall cone of clipped yew. This was to represent the Mount of Olives, and on it was once a clipped figure of the Crucifixion. The whole arrangement follows out a kind of sacred allegory. At the foot of the mount stand the Four Evangelists, and ranged on either side of the grass alleys that form the cross of the T are the twelve Apostles, and the stem is lined with yews to represent the multitude. This is the only garden I know that has a distinct connected idea running through all the clipped work, and is extremely interesting accordingly. Levens, in Westmoreland, has the Kings and Queens of England, and the old heraldic tradition is kept up in the keeper's cottage at Haddon, where the Manners peacock and the Vernon hog preside over hollyhocks and sunflowers. But failing a double interest of this kind, clipped figures are apt to descend into mere trickeries of a clever gardener. With Tudor times passed away the old custom of surrounding the walls of the house with a moat, and water was henceforward used more for ornament and the breeding of fish, than for defence. There are many instances of moated houses of a later date, but in these cases there is generally a small garden of some kind between the house and the water. In the dressed grounds water was always subordinated to the general design, and inclosed within marked boundary lines of stone or brick coping. Large sheets of water such as were made at Wrest or Hampton Court were bordered with turf up to the margin, and so in the pond in the garden at Melbourne, and a smaller piece in a charming old garden at Sydenham, in Devonshire. No doubt in the treatment of it the Dutch influence was strong. Fountains were placed at intervals in the lengths of the water which generally stretched away from the house in the centre of some long vista, and a good effect was sometimes obtained by falls at intervals from terrace to terrace. Perhaps the earliest example of a fountain still existing in England is that with a polygonal basin, that once stood at Cowdray Castle, and has since been moved to Woolbeding, in Sussex. The centre piece of the great Diana fountain in Bushey Park has a curious history. It was originally in the grounds of the palace, and formed the centre ornament in the Privy Garden, where it was seen and described by Count Montcenys in the time of Charles II.; but after this it was taken down, and in 1713 was removed by Sir Christopher Wren to the position it now holds, and a bill is in existence showing that £1,300 were spent in repairs and fixing. Statuary is of the greatest use as a foil to the sombre tone of clipped yew or hornbeam, and perhaps stone or lead seems to be more at home in an English garden, as the lichens and mosses that thrive in our damp climate take to them more readily than the smaller surfaces of bronze or marble. We all know what capital work England produced in wrought-iron gates and railings during the last century. The impetus in this direction came from the work of Tijou, a French smith, who made the great screens for Hampton Court that now stand in Kensington Museum, and are falsely attributed to Huntington Shaw. Their original position was on either side of the avenue leading to the bowling-green, and it is to be hoped the day will come when they may be reinstated there or in some more suitable position at Hampton Court. The influence of Tijou spread all over England, and instances of elaborate wrought ironwork are too numerous to need particularising here. Indeed, each different craft employed in garden decoration would yield

subject matter for a separate paper. The history of a subject of this kind is only the grammar. It forms the rules by which the game is to be played, and that is where we who style ourselves "artists" should differ from those who bear after their names the honourable initials F.S.A. It is not enough for us to know that these things have been, or the exact period at which they were done. The all-important question with us is, What effect had the designer in view, and how may we hope to obtain equally fine effects ourselves? But the practical difficulties that beset the designer nowadays are manifold and almost insurmountable. In the first place, his client being presumably unfamiliar with the history of the subject, will be at least surprised, if not actually shocked, at the suggestion of such a treatment of his grounds. It will strike him that a comparatively small area is to be inclosed, and that the sum to be spent is exorbitant. And it will probably be difficult to convince him that the desired effect can be obtained in a much shorter space of time than if handed over to the landscapist. And another obstacle is the extreme difficulty of any exact estimation of the cost. Personally I have found it impossible so far to carry out works of this description in any other way than by schedule, as the field for design is so unlimited that a fairly free hand is absolutely necessary for success. All this points to the absolute necessity for a generous and cultivated client; failing which, it would be madness for an architect to enter upon any such scheme. And I fear for many years to come regular gardening will remain the pastime of private individuals. It is not likely that public bodies will awake to its charms till this is once more admitted to be the natural and straightforward way of treating the grounds round a building.

Mr. W. ROBINSON, F.L.S., sent a paper, which was read in his absence by Mr. Gale, the hon. secretary. He said: I will confine myself to existing things, and not speak of old books, which have little bearing on the present state of gardens. The architect is a good gardener when he makes a beautiful house. That is a thing for which one must ever be grateful. Whatever is to be done or considered afterwards, one is always helped and encouraged by its presence. On the other hand, scarcely any amount of skill in gardening softens the presence of an ugly building. No one has more reason to rejoice at the presence of good architecture than the gardener and planter, and all stonework near the house, even in the garden, should be dealt with by the architect in every part. But when architecture goes beyond that strictly necessary round the house, and seeks to replace what should be a living garden by an elaborate tracery or pattern-work, error and waste are at work, and the only possible result is ugliness. The proof of this is at Versailles, at the Crystal Palace in great part, in the old gardens in Vienna, at Caserta, near Naples, where there is a far from beautiful stone garden. One may not so freely mention private places as public ones, but many ugly and extravagant things have been done by trying to adapt a mode of garden design essential in a country like Italy, where people often lived for health sake on tops of hills, to gardens in the plains and valleys of England. I know of a terrace in England built right against the house, so as to exclude the light from and make useless what were once the reception-rooms of a great house! That deplorable result came about by endeavouring to adapt Italian modes to English conditions, and was the work of Sir Charles Barry. One of the best places to consider this question is the upper terrace at Versailles, looking from the fine buildings there to the country beyond, seeing how graceless and inert the whole vast design is, how the clipped and often now dying, because mutilated, yews thrust their ugly forms into the landscape beyond and rob it of all grace. To those who tell me this sort of work is necessary to "harmonise" with the architecture I say no, there are better ways; to rob fine buildings of all dignity and repose by a vast geometrical "pattern" is the worst way. Where formal gardening is done on a large scale, its cost and maintenance are monstrous. The uses and construction to any building made to be lived in secures it the care without which it cannot long exist. Even with the support of a State like France the repair of elaborate stonework in gardens is an endless and almost impossible task, as anyone may see who visits frequently that vast extravagance, Ver-

sailles. Nearer home we may see something of the same kind near the huge stone basins of the Crystal Palace. Is it in the interest of architecture that noble means should be so wasted? It is implied by some writers on this subject that "design" can only concern formality—an extraordinary statement. The artistic massing and giving picturesque effect to groups and groves of oak, cedar, or fir is far higher design than putting trees in lines. There is more true and subtle design in Richmond Park and many noble parks in England, where the trees are grouped in picturesque ways, and allowed to take natural forms, than in a French wood with straight lines cut through it. In the old days when designers dealt with but a few trees, and in many countries not a trace of landscape garden existed, it was well to carry the only formal and "decorative design" into the garden. Now a totally different order of things has arisen, because we have tens of thousands of beautiful things coming to us from all parts of the Temperate and Northern world, and people who know these things will not accept a book design, such as Nesfield adopted at South Kensington, instead of our lovely and infinitely varied garden flora. If anything demands special study it is that of garden design with our present materials. If that art is to be mastered the work of a life must be given to it, and more than that, a life's devotion. No less, I presume, is the sacrifice his own art requires of the architect. There is no such thing as a style fitted for every situation. Only one who knows and studies the ground well will ever make the best of a garden. Any "style" may be right if the site fits it. I never see a house, the ground around which does not require treatment, suited to itself only. Many of the terrace gardens out of place shut off the house from the landscape near. That in the case of a beautiful house is often an irreparable loss. The idea in some minds that the old style of building in England was always accompanied by elaborate formal gardening is proved to be erroneous by many beautiful old houses. The Elizabethan house had often an ample lawn in front, or plenty of grass near, as, for example, at Wakehurst. Such houses are quite as delightful in effect as the old houses and castles where terracing was necessary and right, owing to the ground, such as Naworth, Berkeley, Powis, and Rockingham. Large formal gardens are by no means a necessary accompaniment of our finest domestic architecture. Of this there are many instances among the finest old English houses, Tudor and Elizabethan. The idea that trees must be clipped to make them "harmonise" with architecture is a mere survival. Any attempt to keep the gardener out of the garden must fail, as it did in our own day in the case of the ridiculous broken brick and marble flower-beds at South Kensington. Except for what is mostly a very small area near the house, the architect and garden-designer deal with distinct subjects and wholly distinct materials. They should work in harmony, but not seek to do that for which their training and knowledge has not fitted them. If a genius should arise who will master and practise both arts well he will deserve our sincerest felicitations!

Mr. LEONARD STOKES, in proposing a vote of thanks to Messrs. Thomas and Robinson, said the latter writer had well pointed out that the style of garden must be chosen to suit the site, and he would go further and say that it must harmonise with the character of the house. If the building were regular in outline, with a wing on either side, a formal garden was demanded to accord with it; but if, on the other hand, the mansion—for it was of mansions both were speaking—was irregular and picturesque, a more wild and natural type of garden was required. He fancied the cost of large yews was comparatively great. It should not be overlooked that age and association had much to do with the charm of our formal garden, in which there was a risk of vulgarity and dulness if attempted by an untrained hand.

Mr. L. A. SHUFFREY seconded the motion, and claimed that gardens ought to be laid out by the architect of the house. In dealing with small areas the designer of a formal garden needed to have a very free hand. The mistake in suburban gardens was to begin with too many trees and shrubs, which, as they grew, had to be clipped and thinned out. The late Mr. J. D. Sedding has had much influence in reintroducing the fashion for formal gardens; but the pleading needed to be done moderately, or its vagaries were apt to bring ridicule on the custom.

The PRESIDENT, in putting the vote of thanks, said an architect found a difficulty in showing the effect of his proposed garden to his client. A plan was uninteresting and often unintelligible; the old bird's-eye views of Dutch landscapists of the 18th century were open to the objection that they illustrated the grounds from impossible standpoints. The most practicable method was to sketch small portions of the grounds from two or three points, as it would be seen, and submit these, together with a plan.

Mr. INIGO THOMAS, in replying, said it was no doubt difficult for a horticulturist to understand the view-point of an artist, but in one or two particulars he thought the landscape gardeners were coming round to his opinion. He repudiated the idea that a garden was a museum for various kinds of exotic trees, or that there was any beauty in the effect of a nurseryman's grounds. When Mr. Blomfield and he published their book, Mr. Milner and others declared that the views of Knyff and Kyp were much exaggerated; but he had gone over the sites of twelve or fourteen of these gardens, and found, in spite of alterations, proofs that they were very accurate. At Knowle, Ightham, and Rockingham it had been said that there had not been so much stonework as had been reported; but he had found traces of the masonry and statuary still in position. As to what Mr. Stokes had said he held that all houses, whatever their style, were more or less formal, and no house could fail to look at home within the lines of a walled-in garden. As to these formal gardens being only appropriate to mansions, some of the best remaining examples, because they had been least affected by fashion, were those surrounding cottages.

SANITARY VENTILATION.

A PAPER on the above subject was read at the ordinary general meeting of the Surveyors' Institution, on Monday evening last, by Mr. E. Tidman, C.E., M.S.A. The author began by acknowledging that the subject was one of such width that it was quite hopeless to attempt to deal with it completely within the time allotted to a paper such as his own, and he therefore confined his remarks to the ventilation of buildings, sewers, and house-drains. After enumerating the causes of impurity in the air, and insisting on the necessity of constant circulation and renewal of the air of buildings and workshops, as also in sewers and drains, the author went on to state that "natural" ventilation might arise from diffusion, external air currents, winds, or unequal atmospheric pressure. Every degree of heat, he said, dilates the air to the extent of one 491st part of its volume—hence the flow of warm air from the top of a ventilated room, and the inrush of cold air at the bottom. The effect of impure air was admirably illustrated by statistics with regard to cavalry horses. In some old insanitary buildings the death rate was 180 to 197 per 1,000 per annum; but a remodelling and rebuilding of the stables, with the object of introducing a sufficient supply of pure air, reduced these figures in 10 years to as low as 28½ per 1,000. Probably 75 per cent. of the stables in town were in no better state than these originally had been, and the recent outbreak of farcy and glanders was no doubt largely attributable to these conditions. In wet weather the air was, of course, purer than in dry, owing to the washing action of the rain; but under all conditions there were present carbon, sulphur, chlorine, nitrogen, phosphorus, &c., in greater or less proportions. A man in 24 hours gave off 12 to 16c.ft. of carbon dioxide, and to maintain in a state of vapour the 25 to 40oz. of water passed off from the skin and lungs during the same time about 21ft. of air was necessary. The air was vitiated by combustion, 1c.ft. of coal-gas being capable of destroying the entire oxygen of 8ft. of air, and of raising the temperature of 31,290ft. of air 1° Fahr. Ordinary lamps, consuming 154 grains of oil per hour, would deprive 3.2ft. of air of oxygen. The popular belief that impure air descends in a room was fallacious, a simple test showing that the consumed air certainly occupies the upper strata. The safe amount of cubic feet of air per hour per head might be averaged at 3,000—that was to say, 100ft. changed 20 times per hour, or 1,000ft. changed three times. In London lodging-houses 30ft. super or 240ft. cube is allowed per person; in police houses 50ft. super or 450ft. cube. Poor law dormitories are required to give 300ft. to

healthy, and up to 1,200ft. for sick inmates. The Education Department required 130c.ft. per scholar, while the provision for animals should be for horses and cows 1,200c.ft. to 2,000c.ft. Turning to the ventilation of private dwellings, the author pointed out that the objection to "draughts" was the great obstacle in the way of the adoption of any efficient system, and the object of the sanitary engineer must be to get over this difficulty while allowing a full and sufficient supply of air. An ordinary fire drew about 150ft. per minute, and this quantity could be easily supplied by a very moderate opening in a window by the adoption of a bottom bead, say 4in. deep. A "Tobin's tube," of one or another of the forms usually adopted, was also an efficient expedient; while a modification of the same principle, combined with a screen for keeping out dust, &c., and one of Harding's patent diffusers was recommended where the external air was full of impurities and it was desired to get a steady supply without draught. The author's recommendations on the question of hospital ventilation were not new, and might be summed up in the words, "Give each patient as much pure air and as much isolation from his fellow-patients as possible." Public sewers were, he said, more in an engineer's than a surveyor's department of work; but it was not easy to draw the line between the ventilation of public drains and that of house drains. Surface ventilators were most objectionable, and frequently gave off very dangerous effluvia. Lamp-post ventilators were better, and when fitted with gas-burners at their base were excellent extractors; but if by any means the gas became extinguished, the liability to explosion was a serious source of danger. The great fault of most public sewer ventilation pipes was their inadequate size and limited number, and it was evident that in most cases both size and number must be very largely increased before any appreciable improvement in the air circulation of a large sewer could be effected. The author gave statistics and exhibited plans of works carried out at Eston, where a large tall chimney stack was utilised as a ventilator, but where, as some of the subsequent speakers pointed out during the discussion, the effect was shown by Mr. Tidman's figures to be confined to only short lengths of the sewers. The case of East Grinstead was next taken, where every builder was compelled to insert a 4in. ventilation pipe on the sewer side of his trap in his house drain, so that each house did its share of sewer ventilation, and another 4in. pipe at the highest point of the house drain, by which the domestic system was ventilated. This plan was, the author thought, probably the proper one, but this opinion was by no means unanimously upheld by the other speakers, some of whom at least inclined to the belief that the public body should attend to the sewers, and that the householder should only look after his own house drains. Several well-known facts as to the ventilating of house drains having been very clearly and succinctly put forward by the author, and a brief history of the progressive attempts at grappling with the house drain difficult having been given, the paper concluded with the expression of a hope that although the subject admitted of no very new or startling propositions, nor, in the present state of sanitary knowledge, of any novel theories or revolutionary systems, the discussion which followed might elucidate facts and opinions which would be sufficiently valuable to repay the author for his labour in the preparation of the paper.

A discussion followed, in which Professor Robinson, who doubted the efficiency, for any considerable distance, of the chimney shaft system of sewer ventilation, Mr. W. Allport, Mr. H. H. Collins, Mr. P. E. Pilditch, Mr. R. F. Grantham, and Mr. A. Harston took part, and the vote of thanks having been put by the president (Mr. C. J. Shoppee), who occupied the chair, and carried unanimously, the meeting adjourned.

THE "RENDU" OF ARCHITECTURAL DRAWINGS.—III.*

THE student will, on referring back to Fig. 6 in the last article, notice that the scale of tints A B employed for marking off the tint lines on the vertical cylinder or column was taken horizontally on the sphere. In order to model the same cylinder when inclined at an angle of 45° to

* All rights reserved.

the left or to the right, we must employ other scales, for the light, although coming in the same direction, produces different effects, according to the angle of the object. We see this on referring to Fig. 8, where we have the vertical cylinder AB (similar to Fig. 5) and the same cylinder inclined at an angle of 45° either way, as CD and EF. We notice that the lines of tints are different in the three positions; AB is

well lighted, EF is also well lighted, but CD is in half tone. The horizontal line AB on the sphere (divided as in Fig. 6) is, as was explained, the scale for the vertical cylinder AB; EF, marked off from the same sphere, will be the scale for the cylinder EF; and CD that for the cylinder CD. We will notice that the line EF passes across the brightly-lighted portion of the sphere, Fig. 6; a portion of the cylinder EF to which the scale is applied will, therefore, be well lighted; it, in fact, differs very slightly from the modelling of cylinder AB, as will be seen on comparing EF with AB. The cylinder CD, however, differs very much; the scale CD does not cross the well-lighted portion of the sphere, but only the zones more or less in half tone (Fig. 6), and we will notice that the lines *oo*, *oo* of natural shadow are on the extremities of the diameter of the cylinder; the divisions are also exactly symmetrical on both sides. The modelling of the cylinder in these three positions is most useful; the student, after a little practice, will be able to put in the lines of tints without having to use the different scales, his eye becoming habituated to the right proportions of light, half tone, and natural shadow.

We will now deal with concave surfaces, and

explain the method of modelling, say, the curved concave surface of Fig. 9. We will suppose this to be the mould, or hollow, formed by the vertical cylinder (Fig. 5) or AB (Fig. 8). The half

Fig. 10.

cylinder (Fig. 8) is convex, and that of Fig. 9 concave. We shall easily understand that on fitting the first into the second, the different zones of the first will correspond with similar zones in the second, remarking, however, that the zones are reversed, that of the natural shadow *oo* of AB being to the right, whilst that of Fig. 9 is to the left. We may, therefore, use the same scale AB for the concave surface, but reversed, the negative zones 0-1, 2-3 being to the left in Fig. 9, whilst they are to the right in Figs. 8 or 5. In all concave surfaces there must necessarily be a cast shadow, as shown in Fig. 9; the surface being the half of a circle, the shadow is cast as far as the centre line at B, the quarter circle confining the shadow thrown by the soffit BA is drawn from the centre of BA, as is seen in the drawing. The tinting of this concave surface is similar to that explained for Figs. 5 and 7, only we must take into account the effect of the cast shadow. As we have already learnt, an object or zone in cast shadow will be darker in proportion as it would have been bright if the cast shadow did not exist—that is to say, the zones 1, 2, 3, 4 being in cast shadow will be dark in proportion as they were bright in Figs. 8 or 5. This effect may be observed in shadowed drawings; an object which when in the light appears more or less bright, when immersed in cast shadow should appear all the darker and more forcibly indicated.

Let us now model the series of mouldings in Fig. 10. The student, after having studied the convex and concave surfaces of the preceding figures, should find little difficulty in correctly modelling the various mouldings.

Mouldings 1 and 2 are simply convex or concave half cylinders of an unpolished material. We have the four principal zones—first, that of natural shadow; second, that most brightly lighted; third, that of local colour; and fourth, those of the half tints forming the transition between the light and shade. The first three zones are sufficient to model the mouldings; but as here the scale is large, we will employ the six lines of tints as used for the cylinders. For mouldings 1 and 2 we will employ the scale of tints AB (Fig. 6). The zones will be exactly proportional to those in the half cylinders, Fig. 5, AB, Fig. 8, and Fig. 9. We notice that the brightest zone, if between the lines 6, 6, is where the rays of light strike in full, as indicated by the arrows. The line *oo*, where the natural shadow begins, is at the tangent point of the line drawn at 45° . The cast shadow in the concave surface 2 is limited by the line drawn at 45° from the upper projecting portion of the moulding. For the mouldings 3, 4, 5, and 6, we find the cast shadows by means of the light lines at 45° from the projecting portions. The tangents at 45° will give us the zones *y*, the brightest portion of the mouldings, as indicated by the arrows. Mouldings 3 and 5 have no tangent points; the zone *y* is therefore absent in these

two examples. The natural shadow line *oo* is given by the tangents, as in mouldings 1 and 3. The zone *x*, or zone of local colour, is given by the tangent drawn vertically to the mouldings; the vertical surfaces, and those approaching the vertical, marked zone *x*, between the lines 5, 4, are, therefore, in local colour. Thus we have, in moulding 3, firstly, a narrow shadow cast by the projecting fillet (this being a vertical surface is in local colour); then the zone 5, 4, which being tangent to the vertical is also in local colour; then comes the graduated tints as far as the tangent point *o*, where the natural shadow commences. Moulding 4 is brightly lighted at the tangent point; the zone 6, 6; the zones 6, 5, 4 are in local colour. Again, the moulding 5 has its cast shadow as far as zone 3; the zones 3 and 4, being nearly vertical, are in local colour. Moulding 6 is in local colour as far as zone 6, gradually brightening, or, rather, becoming lighter, on approaching the brightly-lighted zone 6, 6.

When tinting these mouldings we must not forget that, as we have said before, a zone which is in cast shadow should be made darker in proportion as it would have been bright if the cast shadow did not exist. The first light tint is passed over all shadows, whether cast or natural; the colour tints are then washed over, gradually darkening as the negative zones are approached. The cast shadows are then put in, care being taken to produce the effect spoken of about zones in cast shadow. The shadows cast on the vertical planes should equal in intensity the tone of the zones on the mouldings nearly approaching the vertical, at 5, 4, or zones *x*. A little practice, and a careful attention to the principal zones of light, half tone and shadow, will enable the student to model effectively all kinds of mouldings.

ARTHUR VYE-PARMINTER.

GOTHIC ARCHITECTURE.*

MR. WALTER ARMSTRONG'S translation of M. Edouard Corroyer's work on Gothic architecture is a volume that will be read with interest by all architectural students. M. Corroyer, inspector of diocesan edifices, writes from a French standpoint; he regards every Gothic development of importance as having a Gallic origin, and he traces to French influence the most remarkable edifices of English Gothic. These views will be questioned, no doubt, though the value of the treatise as a clear exposition of the evolution of Gothic will remain. What the English student will most regret is the want of examples in his own country, those described and illustrated being mainly French. The author writes: "The architectural period which began in the middle of the 12th century, and is so unjustly dubbed Gothic, was of purely French

* Gothic Architecture. By EDOUARD CORROYER, Architect to the French Government. Edited by Walter Armstrong. London: Seeley and Co., Limited, Essex-street, Strand.

birth; its cradle was the nucleus of modern France. Aquitaine, Anjou, and Maine, were the provinces in which it first took root. The Royal Domain and notably the Ile-de-France witnessed its most marvellous developments, and it was from the very heart of France that its splendour radiated throughout Europe." This sentence is the keynote of the author's argument—all developments of Gothic may be traced to Romanesque, and the groined vault itself had its embryo in the pendentives of the dome of St. Front, and the architects of the Ile-de-France were the first to adopt it, and subsequently invented the flying buttress. The cupola of St. Front, though borrowed from a church at Constantinople, was thus an original development, and was the germ of the groined vault and its system of buttressing throughout Western Europe, though the flying buttress was more timidly introduced, especially in the South. M. Corroyer says little about the bolder flights of construction in the North in which the flying buttress was used.

As the dressed stone cupola of St. Front is claimed to be the origin of the intersecting arch, no anterior Roman vault can be accepted as an explanation, but of this further proof is required. A plan and sketches of the pendentives and cupolas of St. Front, and plans and sections of the cupolas of Angoulême are given to illustrate this point, and other steps towards the development of the intersecting vault, as we see in the churches of Angers and Laval, illustrative sketches of which are given. In the third chapter one or two mistranslated terms occur; one of these is the word "ossature," which would have been more correctly translated *skeleton*. The author takes particular pains to prove the identity of the function of the pendentive with the Gothic intersecting arch, and that the cupolas of Angoulême developed into the groined domical vaults of the church of Angers. We are next shown examples of the intersecting vault system, such as the view of a church near Avignon, the nave of St. André at Bordeaux, St. Etienne at Toulouse. The church of La Ste. Trinité at Angers is illustrated, and is a fine instance of the transformation. All the great abbey churches and cathedrals of the latter part of the 12th and of the early part of the 13th centuries show the development of the system; the bays were square, and each was divided by a transverse arch, carried by shafts, as at St. Trinité, Angers. Out of this system grew the flying buttress, which forms the subject of a separate chapter, and is illustrated by sections of Durham, Noyon, Soissons Cathedrals. Churches and cathedrals of the 12th and 13th centuries are discussed, and well-engraved sketches and sections are given of Leon, Notre Dame, Sens, Bourges, Rheims, Amiens, Chartres, Mans, Beauvais, Lichfield, Lincoln, and other cathedrals. Those of the 14th and 15th centuries follow. The other chapters deal with towers and steeples, choirs, chapels, sculpture, painting. Part II. takes up monastic architecture, and Part III. military architecture, while a concluding section is devoted to civil architecture, a few good engravings of which are given.

ALMANACKS AND DIARIES FOR 1893.

FIRST and foremost, as usual, undoubtedly are the Architects' and Builders' Diaries, and the Registered Date-Indicating Blotting-Pad of Messrs. Hudson and Kearns, of 83, Southwark-street, S.E., which are now to be found in every well-appointed office. The luxuries of one age become the necessities of another, and our own recollections, alas! carry us back to the times when these aids to business, which are now indispensable, were not to be had for love or money. All we can say is, as we write up the memoranda in the one particular Indicator we reserve for our own desk, that we cannot realise how a quarter of a century ago we did without it.

One of the handsomest wall calendars for 1893 we have seen is issued by the Rugby Portland Cement Company, of Rugby. There is a useful detachable monthly date-card in the centre. Above is a well-coloured view of the works at Rugby, and all round are an instructive and nicely executed series of geological views, illustrating successively an ideal view of a marshy forest during the coal period, a landscape of the Upper Oolite period, the Silurian period, the Eocene period, the Liassic period, the Eocene period, and the Upper Cretaceous period. Below

is a Geological section across England from Holyhead to Dover, and above that is a view of part of the quarry at Rugby.

THE "CHAMPION" COMBINATION WATER-CLOSET.

MESSRS. WRIGHT, SUTCLIFFE, AND SON, of Globe Sanitary Works, Halifax, have introduced to the trade their "Champion" combination water-closet, which is in pedestal form, but constructed on the wash-down principle. For solidity and strength it will compare favourably with any in the market. The material chiefly used in the manufacture is extra strong fireclay, obtained from one of the best-known sources in Great Britain; porcelain enamelled buff outside, and white inside. It is made on the soundest principles of sanitation, and is undoubtedly one of the best and safest closets ever introduced. It has a straight back outlet, and possesses a good water seal, which makes it most reliable and certain against sewer-gases. The cup of the basin always retains a water-depth of 5in. While embracing these advantages, its working power is safer and more effective than the ordinary wash-out closet, as only a flush of 2 gallons is needed. When

flushed, the force of the water is brought to play directly on to the contents of the trap, insuring a complete clearance therefrom. The strength of the water is not impaired, as in other types; but, by a peculiar arrangement in construction, the water is conducted to play on the trap immediately it enters the basin.

The closet has already received the approval of a large number of architects, sanitary engineers, builders' merchants, plumbers, &c., and the sales are continually increasing.

It is specially adapted for use in outside buildings, public works, barracks, factories, warehouses, schools, prisons, and other places where strength, durability, and cleanliness are desiderata.

We are informed that they have been favoured with orders from a number of local boards and other public bodies, who express their satisfaction with the efficient working of the closet.

This closet can also be supplied with the inside formation on the wash-out principle.

METROPOLITAN IMPROVEMENTS.

THE Bill of the London County Council providing for the making of new streets and street improvements, the rebuilding of Vauxhall Bridge, and the establishment of a ferry between Rotherhithe and Ratcliff, has been deposited at the Private Bill Office, as required by the Standing Orders of Parliament. The Bill sets out the estimates of the cost of the new Central-street and subsidiary streets between Holborn and the Strand at £3,869,550; the approach to Tower Bridge, £436,000; the widening of Wood-lane, Hammersmith, £47,215; Vauxhall Bridge, £484,000; Rotherhithe and Ratcliff Ferry, £483,000; widening approach to south side of Woolwich Ferry, £3,000; and there is added £45,000 for cost of sites for rehousing displaced persons, making a total of £5,327,765. In addition to the new street from Southampton-row to St. Mary's Church in the Strand, the Council propose to set back the railings around the church and throw into the widened roadway part of the

enclosed ground at the west end of the church, to form a junction roadway at the southern end of Central-street, making a double junction with the Strand on the east and west side of St. Mary's Church, and to remove the block of buildings between Holywell-street and the Strand. A new or widened street following the line of Wych-street is to be made, which will form a junction with the new Central-street, and other streets are to be made from the latter street to the south-west end of Houghton-street and the south-western corner of Lincoln's Inn-fields. In connection with the Tower Bridge approach there are to be widenings and new roads made, and the railings around St. Mary Magdalen's Church, Bermondsey, are to be set back. Provision is to be made for the erection of a temporary bridge at Vauxhall while the existing bridge is being demolished and the new one built, and over the new bridge power will be taken to lay tramways. The time for the acquisition of the property for the new Central-street improvement is limited to five years, and for the other improvements to three years. A feature of the Bill, which will probably prove fatal to its success, is the provision for the imposition of an "improvement charge" upon adjoining property in respect of all the works other than the Wood-lane widening.

In addition to these Bills, the London County Council have deposited at the Private Bill Office a General Powers Bill. One provision in the Bill has reference to the prohibition of the erection of dwelling-houses on low-lying land, which is below the level of Trinity high-water mark, or which is subject to flooding, or which is so situated as not to admit of being drained by gravitation into the existing main sewerage system. Provision is made in the Bill for compensation to workmen who are injured by working with the compressed air in the formation of the Blackwall Tunnel. Other clauses amend the definition of sky-signs, and provide for lighting the Victoria Embankment and Waterloo and Westminster Bridges by electricity.

CHIPS.

The Directors of the Highland Railway have received an intimation that the Government has resolved to contribute a sum of £45,000 towards the cost of extending the Highland line from Strone Ferry to Kyle, a distance of 10½ miles, and constructing piers on both sides of Kyleakin Ferry.

It is proposed to commemorate the jubilee of the consecration of St. Catherine's Church, Barton-on-Irwell, by erecting a new chancel and carrying out other alterations in the structure, at an outlay of £1,630.

The new building for the Spanish Reformed Catholic Church in the Central Park, Madrid, has been consecrated by the Archbishop of Dublin. It consists of three parts, the central of which is a church, that on the right being synodical halls and schoolrooms, and that on the left a pastor's house. The church is Byzantine-Gothic in style, and is about 60ft. long by 35ft. broad, with an apse. The cost of site and buildings adjoining was about £10,000.

The extended time granted for the construction of the Tower Bridge expires in August next. Though, at the present moment, the engineer, Mr. J. Wolfe Barry, is confident that the bridge will by then be ready for opening, the Bridge House Estates Committee, with a view to providing against contingencies, purpose in their Bill asking Parliament to extend the time by a further period of one year—viz., till August 12, 1894.

Lady Alice Ashley opened on Saturday a model lodging-house for men in Macklin-street, Drury-lane, which has been erected by the Society for Improving the Condition of the Labouring Classes. The site cost £1,325, the new building £2,157, and the furniture £250, making a total of £3,732.

The Cardiff Town Council have advanced another stage in the proposal to build new Municipal Buildings, Post Office, and other public institutions on a portion of Cathays Park. The Marquis of Bute has written offering to sell 38 acres of the park (which has a total area of 59 acres) for a sum of £120,000, being at the rate of £3,158 per acre. The various public bodies interested have been wanted to appoint representatives to confer with the Town Hall Committee, and to appoint a joint deputation to interview Lord Bute's agent, and arrange terms.

Wings are being added to the Congregational schools in Water-lane, Radcliffe, Lancs. The buildings provide four class-rooms, the largest being 33ft. by 22ft., and the cost will be £700. Mr. Smith, of King-street, Manchester, is the architect, and Mr. J. Rigby, of Radcliffe, the contractor.

ANTWERP CATHEDRAL.—NEW PREMISES OF SIR JOHN BENNETT, LIMITED, CHEAPSIDE.—CHAPEL OF UNIVERSITY COLLEGE, DURHAM.—STALLS, SCREEN, AND GALLERY FOR PRINCETHORPE PRIORY.—SEMI-DETACHED HOUSES, BELFAST.—ST. PHILIP'S CHURCH, STEPNEY.—ST. SAVIOUR'S CHURCH, WESTON-SUPER-MARE.—CAST-IRON MANTELPIECES.

Our Illustrations.

ANTWERP CATHEDRAL, FROM THE PLACE VERT.

THE Cathedral of Notre Dame, Antwerp, is one of the most remarkable and extensive churches to be seen in the Netherlands, with its lace-like steeple and silver-toned bells, dominating the town in which it forms the chief and naturally the most important object, both for scale and interest. We give to-day a view by Mr. J. R. Hutchinson, of Westminster, showing the building from the Place Vert, with the familiar statue of Rubens in the fore part of the picture, and we have to add that our illustration is taken from the large etching published for the artist by Messrs. Clifford and Co., of Piccadilly. The south transept just comes into the sketch, and the deep aisle roofs are just seen over the tops of the inclosing houses. It may be interesting to note here that the architect of the spire was Jan Amelieus, who began the work in 1422. It was finished by Appellmaus, of Cologne, in 1518. The steeple is one of the loftiest in the world, being 404ft. high. It contains sixty bells, the "Carolus" weighing 16,000lb. The view from the upper gallery extends to Flushing, Mechlin, Brussels, and Ghent, and commands the river Scheldt.

LXV. CHEAPSIDE, E.C.

THE refitting of these premises for the directors of Sir John Bennett, Limited, were executed during the summer by Messrs. John Grover and Sons, contractors, from the designs of Mr. A. Burnell Burnell, F.R.I.B.A., Eflingham House, Arundel-street, Strand, W.C. The old frontage was reduced by half, but the striking figures (so well known for their advertising capabilities) had to be retained, which, no doubt, to some extent dwarfed the new elevation.

UNIVERSITY COLLEGE CHAPEL, DURHAM.

THE Castle of Durham, formerly belonging to the Bishop of the Palatinate, was in 1834 given to the then recently-founded University, and is now "University College." The original chapel of the castle was built during the episcopate of Bishop Flambard, Chancellor to William Rufus; but it appears to have been disused early in the sixteenth century, when the present chapel was built by Bishop Tunstall about 1540. It is, as will be seen from the drawing, of the very latest Perpendicular work, but, like the rest of Bishop Tunstall's work, is of considerable character. It was originally only 37ft. long, but after the Restoration Bishop Cosin lengthened it by 20ft., moving out and replacing Bishop Tunstall's east window, and at the same time panelling the open roof. At the west end is a somewhat remarkable screen, also the work of Tunstall, but altered by

Bishops Cosins and Crewe. There are also some exceedingly fine stalls and desk ends, originally put into the chapel at Auckland Castle during the episcopate of Bishop Ruthall, 1509-1522, but moved to Durham by Tunstall, who records the fact in his accounts:—"1547-8. To Robert Champne, Esq. 17 days in takyne downe of the stalls in the hye chapel and sortynge of them, and dyghtinge and dressinge of them, and helpynge to conveye them to Durran." When the castle was handed over to the University the chapel appears to have been in a somewhat dilapidated state, and it was then partially refitted with stained deal, and the east end panelled with some remarkable inlaid work from the great pulpit of the cathedral, then recently removed. This work has now been placed in the cathedral library. A few years ago the present Master and Bursar determined to restore and refit the chapel, and the first work undertaken was the rearrangement of the old stalls, and completing them with new work, the western screen being at the same time moved further back into the ante-chapel to accommodate the increased number of undergraduates. Next followed a new marble pavement, and then the altar and triptych shown in the view, together with panelling round the east end, and the work has been completed this year by panelling with oak the rest of the chapel. The triptych is exceedingly well carved, the figures in the centre representing Our Lord crucified, Our Lady and St. John, and St. Longinus and St. Mary Magdalene. The doors have also excellent figures in bas-reliefs of SS. Ambrose, Augustine, Cuthbert, and the Venerable Bede. The altar now has angels painted in the panels. All these works have been designed by and carried out under the personal direction of Mr. C. Hodgson Fowler, F.S.A., M.A., of Durham.

ST. MARY'S PRIORY, PRINCETHORPE, WARWICKSHIRE.

MESSRS. JONES AND WILLIS, of 43, Great Russell-street, and Birmingham, have lately completed the oak stalls for the conventual church of St. Mary's Benedictine Priory, Princethorpe, Warwickshire, from the designs of Mr. Joseph Stanislaus Hansom, F.R.I.B.A., of 27, Alfred Place West, South Kensington. The work involved the removal of the old stalls, which were erected over thirty years ago from the designs of the late Mr. Joseph Aloysius Hansom; the removal of a dark and clumsy ante-chapel, with two lateral doors instead of the present central one; and a deep gallery where the organ formerly stood, and the substitution of the new screen and gallery, shown in the view; also a general rearrangement, so that now the organ is in a new side gallery, whilst the manual is close to the nuns' stalls. By this rearrangement seats have been obtained for twenty-five more students from the high-class school conducted by the nuns. Special care had to be taken not to interfere with the consecration crosses on the side walls, which would have entailed a fresh consecration; and it was, therefore, necessary to arrange the bays of the upper part of the stalls quite irrespectively of the width of the stalls themselves. The effect is more perceptible on paper than in the actual work.

SEMI-DETACHED HOUSES, BELFAST.

THESE houses have just been completed in the north of Ireland. The exterior treatment of the walls is in local red-facing brick, with some of the upper portions in plaster work, the roofs being covered with Ruabon red tiles. Mr. F. E. Ward, A.R.I.B.A., of Belfast, was the architect, the contractor for the work being Mr. Robert Corry, of the same city.

ST. PHILIP'S CHURCH, STEPNEY: DETAIL OF CHOIR ARCADE.

THERE is no more to add to our previous description of this church when giving, during the past few weeks, the plan, views, and general drawings of the buildings. This sheet is a copy of one of the architect's working plans, and it shows the arcade in the choir, the choir aisle, and the transepts, to which is added a plan through the passage of the triforium. A reference to the general plan of the church will enable the reader to follow these details more correctly. It was given in the BUILDING NEWS on December 2. Mr. Arthur Cawston is the architect.

ST. SAVIOUR'S CHURCH, WESTON-SUPER-MARE.

THE first portion of this church, now completed, was recently opened by Bishop Bromby. The

external walls are of local limestone with freestone dressings. The interior (except the chancel, which is cased with freestone) is lined with buff bricks, with Bath stone dressings and red rubbers for bands and vousoirs of arches. The shafts of the arcade columns are of red Mansfield stone. The church, when completed, will provide seats for about 300 persons. The designs, which were selected in competition, are by Mr. Sydney J. Wilde, architect, of Weston-super-Mare.

CAST-IRON MANTELPIECES BY THE COALBROOKDALE IRON COMPANY.

ALFRED STEVENS did many things besides the Wellington Monument and the decorations at Dorchester House. Time was when he was glad to be employed by manufacturers to furnish designs and models for articles of domestic use, and it is hardly sufficiently well known how many such articles he enriched with his genius. The Coalbrookdale Company were early alive to the beauty of his work, and they possess the models of the only two fireplaces he ever is known to have modelled for reproduction—of course, leaving out of the question the Stevens Fireplace at Dorchester House. We have deemed it likely to be of interest that we should illustrate these two fireplaces; the figure one is especially characteristic of the "Master." We have also added two little interiors in good style by Mr. Faulkner-Armitage, made by the same firm of manufacturers, which are good specimens of modern work to current taste.

CHIPS.

A large collection of weapons and armour has been bequeathed to the Artillery Museum at Paris by the late Col. Lichtenstein.

The Royal Victoria Hospital at Bournemouth, which was opened in January, 1890, has just been enlarged by a wing providing six additional beds, making thirty-one in all. The architects were Messrs. Creeke and Gifford, of Bournemouth. The new wing was opened by the Duke of Connaught on Monday. We illustrated the hospital in our issue of Jan. 17, 1890.

The Flintshire County Council have decided to co-operate with the Cheshire County Council and the River Dee Conservancy Board in erecting a bridge over the Dee at Queensferry, Hawarden, and to contribute £5,000 towards the estimated cost of £13,000.

The redecoration of St. James's Lower Hall, for Messrs. Moore and Burgess, has been intrusted to Messrs. Campbell Smith and Co., of Newman-street, W.

The Bibliothèque Nationale, Paris, has acquired a manuscript treatise on architecture in six chapters by Jean Goujon.

Dr. William Dorpfeld, the principal of the German Archaeological Institute at Athens, has resumed his excavations on the south-west side of the Acropolis, with the aim to trace the celebrated fountain of Kallirrhoe.

A white marble monument has been sent to Spain to be erected over the tomb of the late Mr. E. A. Freeman. It bears an inscription, "To the pious memory of Edward Augustus Freeman, who enshrined in letters for all time the early history of England, the Norman Conquest, and the destinies of Sicily. Fired with a zeal for topographical research, he was struck down in the midst of a journey in Spain by sudden sickness, and died there March 16th, 1892."

An Edinburgh firm of silversmiths has just executed, from designs by Mr. John Hutchison, R.S.A., a set of communion plate as a memorial gift to St. Salvador's Church, St. Andrew's (the College Church), by one of its members. The service, consisting of a massive flagon, two cups, and a paten, is in the Early Seventeenth Century style of work, with something of the feeling superadded of the Gothic form of the fifteenth century. Each piece is octagonal in form throughout, except the cups, which pass into the round at the lip.

In order to comply with the requirements of the town council of Leeds, the Theatre Royal in that town is about to be altered and provided with new dressing-rooms and green-rooms. Mr. Fowler, of Leeds, is the architect, and the estimated outlay is £2,000.

The Manx Tynwald Court, at its meeting on Friday, granted leave to the Douglas Town Commissioners to borrow £50,000 for the purpose of the town improvement scheme, which deals with the reconstruction of the old part of the town, pulling down a great deal of insanitary property, and erecting artisans' dwellings. The Ramsey Town Commissioners obtained leave to borrow £3,000 to complete their sewerage scheme.

CAST-IRON MANTELPIECES MADE BY THE COALBROOKDALE IRON COY FROM DESIGNS BY THE LATE ALFRED STEVENS & OTHERS

DELLAGANA S.

E. Chancellor Del.

WAYSIDE NOTES.

IN a column of "ecclesiastical intelligence" in the *Morning Post* of Monday were several items of news interesting to architects. First, as to St. Helen's, Bishopsgate, the work of restoration under Mr. Pearson's direction is now well advanced, but subscriptions are required for the completion of the scheme. A donation of £1,500 towards the fund has been offered on condition that the remaining £1,700 is immediately raised by the rector and churchwardens. Then we learn that the roof of old Arundel Church, *temp.* 1380, has become so honeycombed by the ravages of some insect as to be in a dangerous state, so much so, that it must be replaced. Next it is proposed to rebuild the nave and tower of St. Mary's, Harlow; while a proposal is under consideration for the complete rearrangement of the interior of the parish church of Great Baddow, Essex, the scheme including the removal of the galleries, the rearrangement of seats, the provision of a choir vestry, and "other improvements" at a cost of £1,000.

Lord Meath, as chairman of the Metropolitan Public Garden Association, has done much to improve the condition of London in respect to its open spaces. In his lordship's letter to the *Standard* of Wednesday is set down the nature of the work accomplished by this Association. During the past summer the Association completed and opened to the public no less than seven grounds, including important churchyards like Soho and Spitalfields, thus directly adding nearly six acres to the open spaces of London. In nine years over 70 grounds, scattered all over the metropolis, have, through the instrumentality of the Association, been thrown open to the public. Appeals for assistance to lay out the closed portion of Hackney churchyard, Woolwich parish churchyard, St. Thomas-square, Hackney, and a playground in Kentish Town, have been received. If these undertakings are proceeded with, now is the time for action, that the grounds may be ready for the enjoyment of for the people in the ensuing summer. In his appeal for donations to a good work Lord Meath need not have made any apology. The public authorities he refers to prefer apparently amusing themselves with trying experiments and making airy schemes. The real work in the way of securing open spaces among crowded populations has been done by the Metropolitan Public Gardens Association.

Further estimates in connection with the Asylum at Claybury were before the County Council on Tuesday, and they show the enormous scale upon which the building has been arranged. A sum of £17,500 had been provided for the electric lighting of the asylum. This in itself is considerable; but a further amount being required, the Council have sanctioned additional expenditure on this item of the works at Woodford Bridge.

Respecting the recent accident with a derrick at the corner of Ludgate-hill, Messrs. Ransomes and Rapier, of Ipswich, write to the *Times* of Wednesday, suggesting that steel-wire rope should be employed in place of the chain that controls the radiating power of the jib of the derrick. A jib of 50ft. or 60ft. weighs some two tons, and is usually raised and lowered by a chain. Chains, say the writers, are not reliable for such purposes, a chain lifting ten tons one day having been known to break next day with only a two-ton load. The steel-wire rope being composed of many strands, when one strand breaks it "frays out" and thus gives timely warning long before a point of danger is reached. A pair of ropes, each strong enough to do the whole working duty are recommended, and as steel wire ropes are relatively inexpensive to purchase, a working factor of ten or twenty times the safe limit of strain can be adopted. Seeing how wide is now the use of the steam Scotch derrick in London, this is a point deserving the attention not only of builders and contractors, but of those authorities having the care of the public using the highway in their charge. Derricks always look dangerous, and, as frequent sharp reminders prove, are in reality so, unless every precaution is taken to prevent an accident either from instability of the stagings on which they are erected, or from failure in some part of the machinery or gear. The Ludgate-hill accident very nearly proved of a most

disastrous character. To prevent the realisation of what might here have been possible, active measures should be taken. It is the duty of the London County Council to look after the safety of the public from accidents arising from building works in the street, and the Council may be losing sight of this, its duty, while occupied with the inauguration of municipal building schemes which nobody fancies, and which may prove an expensive experiment for the ratepayer.

Returning from a few days in the provinces, I have to burrow my way through the shoal of Xmas almanacs already coming to hand. Two beauties I have at once displayed. One—a calendar of the movable order—occupies a commanding position on the mantel-shelf, and having much silver lettering, and being withal of shield-like outline, presents an imposing appearance. The other is prepared more on the principle of quantity as against quality, and as temporarily hung blocks up a little of the view of Wales in my renowned map, so that it being impossible to see Pembrokeshire, in the event of my receiving a wire to build a cathedral in any town of that westerly corner of the Principality, I should be unable to locate the spot at a glance. The obstruction, therefore, cannot permanently remain; so either it must be destroyed, like Carthage, or I must call upon the generous donors to remove the bauble, in correct and Cromwell-like manner. What other blessings may be in store this festive season remains to be seen. Certainly the manufacturers are this year very thoughtful and considerate. With the silvered shield there came to hand a brass-headed nail of great tonnage, which, though scarcely of the tenpenny order, yet is a cousin-german thereto. Furthermore, the other day arrived a substantial, well-varnished card of divers goods and chattels, and with it a wall-hook for convenience of attachment to walls.

I have had a run in the Shropshire district, visited by the Architectural Association last year, and although Friday afternoon till Tuesday evening would, of course, not enable me to see all the places visited during that excursion, we yet managed to get in a ramble over the Wrekin from Welling to Buildwas Abbey, and so on to Much Wenlock, which, if I remember rightly, the Association excursionists—so far as concerns the Wrekin—had to forego from stress of weather. It is, perhaps, not inconsistent in our latter-day British climate, that where the rain spoiled a trip in August, in mid-winter we had dry, balmy, and bright weather, with a sun shining on the wide-spread Salopian levels, as seen from the dark head of the noble Wrekin. Beautiful Buildwas and grand old Much Wenlock Priory came in for examination—ruins deserving all the enthusiasm that their contemplation provokes. Ludlow we duly inspected and found its renowned castle all too beautiful for a short visit; nevertheless, personally speaking, I have a very clear recollection of its bold architecture, its great keep, banqueting-hall and kitchen, its beautiful entrance doorway from the great green square, and the grand old timber that still surrounds the walls. Of Stokesay I cannot say sufficient to impress the reader. Nothing pleased us better, and I should only like to see the old castle again when, in place of the wintry background of sombre purple hills, the grey stone walls would rise above masses of pink-and-white apple-blossoms in the surrounding orchards. Another feature of our outing—not, I believe, included in the Association programme—was a fifteen-mile trudge from Church Stretton, over the lonely Longmynd moors and the rugged rocks of the frowning Stiperstones, to the village of Minsterley. The Shrewsbury black-and-white houses I saw and admired in a respectful way, as I have at another time admired the old Domestic architecture at Chester, without, however, the least desire to imitate either the one or the other. Shrewsbury architects have been of another mind: there are several very good modern street fronts in the old black-and-white style. To judge, however, from works in progress, the style is not at the present moment in fashion at Shrewsbury.

A Right Merrie Christmastide to all, from
GOTH.

Professor J. Henry Middleton, F.R.I.B.A., of King's College, Cambridge, and Cheltenham, married at the British Embassy, Rome, on Saturday, the daughter of Mr. W. J. Stillman, of that city.

OPERATIVE PAINTERS' CONFERENCE.

FOR the furtherance of technical education in the painting trade, a united conference of masters and workmen has been arranged to be held in Painter Stainers' Hall, Little Trinity-lane, E.C., on Monday, Tuesday, and Wednesday, January 16, 17, and 18. A strong organising committee has been formed, with Mr. W. G. Sutherland, of Manchester, as chairman; Mr. William Foulness, of the Technical Schools, Finsbury, as treasurer; and Mr. George Kilpack, the president of the affiliate Societies of Operative Painters, is hon. secretary. The meetings will begin each evening at half past five o'clock. On the first evening, papers will be read on "The need of better and more Systematic Training on the part of Members of the Trade," by Mr. W. G. Sutherland; "How Best to Stimulate an Interest in our Trade on the part of the Young," by Thos. Lough, M.P., and Mr. W. A. Steward; and "Is it Desirable to Revive the Apprenticeship System," by James Clarke, Edinburgh. On the Tuesday evening, Lieut.-Col. Robert J. Bennett, Glasgow, will deliver an address; and a discussion on "Trade Classes and their Management" will be introduced by Messrs. T. G. Millis, M.I.M.E., and Wm. Fourniss; to be followed by one on "Is it desirable to Establish a System of Registration or Enrolment, and to Grant Diplomas of Ability?" introduced by Mr. Geo. Kilpack. On the Wednesday evening, Mr. J. D. Crace will preside and deliver an address; after which some proposals for establishing a new organisation will be introduced by Mr. A. Chappell.

OBITUARY.

Mr. John Haggard, for more than forty-two years one of the officials at the Museum of Geology, died at his residence in Fulham, on Friday, in his 80th year.

Mr. Alfred Fryer, of Wilmslow, who died on the 13th inst., aged 62 years, was the inventor of the well-known destructor for the burning of town refuse. His papers on "The Influence of Forests on Rainfall" awakened popular interest in the subject, and resulted in the systematic preservation of trees in the West Indies.

The death took place on Wednesday week of Mr. Lyons Wright, C.E., many years engineer and manager of the Corporation Waterworks at Wolverhampton. The deceased gentleman was a native of Hull, and after being engaged in Manchester, went to Wolverhampton 30 years ago as engineer to the Waterworks Company, and on the concern being acquired by the Corporation he retained his position until last June, when he retired, and was appointed consulting engineer. Under his management the waterworks system was extensively developed. The late Mr. Wright was regarded as a very energetic servant of the Corporation, never having had a day's holiday. He was a prominent Freemason, and also an ardent amateur photographer. He had been a widower for many years, and has left an only daughter. He was in his 69th year.

Mr. Dobell, of Exeter, has been instructed to prepare plans for converting the town-hall at Crediton into public rooms and a home for the District Constitutional Club.

Among the Volunteer officers of senior rank in the Home District to whom the decoration just granted by her Majesty for long service and efficiency was presented by the Duke of Cambridge on Monday were Sir Frederic Leighton, P.R.A., Hon. Colonel of the 20th Middlesex Artists' Corps, and Col. R. W. Edis, F.S.A., who commands that corps.

Henry Stubbs, a contractor, of Lambeth, was charged at the Guildhall, on Friday, with gross cruelty to a horse by causing it to be worked whilst lame. Stubbs had been previously convicted, and fined the full penalty, for cruelty to horses. Sir Andrew Lusk sentenced the defendant to prison for one month with hard labour, but notice of appeal was given.

Messrs. Maxwell and Take, of Manchester, report satisfactory progress with the erection of the Blackpool Tower, which is now completed up to 55ft., and three of the pillars are fixed up to 85ft. high. Up to the 10th of December 785 tons of iron and steel had actually been erected. It is possible now to form an idea of the appearance of the circus underneath the tower. This room will be 110ft. square, and between 40ft. and 50ft. high.

DRAINING AND PLUMBING SPECIFICATION.—III.

By ARTHUR BAKER, F.R.I.B.A.

VENTILATING PIPES.

103. **SIZE OF VENT-PIPES.**—Ventilating pipes, unless otherwise described, to be the full bore of the pipe which they ventilate.

104. **Main anti-siphonage pipe:—**

Provide and fix to the branch pipe of the lowest w.c. or slop closet a in. lead anti-siphonage pipe, and connect ditto with soil-pipe ventilating pipe at a height of 12in. above the top of the basin of the highest fitting, and connect all anti-siphonage pipes from fittings with this pipe. (See Fig. 21. See also Clause .)

105. **Anti-siphonage pipe to branch soil and other pipes:—**

Anti-siphonage (or vent-pipe) to branch soil, sink, or other pipes to be fixed near the outgo of trap, and to be slightly bent at the junction in the reverse direction to the flow of the water (see Fig. 21), and connect ditto with main

FIG. 21

anti-siphonage pipe above the level of the top of fittings. Anti-siphonage pipe to branch soil-pipe must be connected with soil-pipe ventilating pipe, and not with bath or lavatory ventilating pipe, or vice versa.

106. **Cross-bars to vent-pipe:—**

Ventilating pipes carried through wall, unless otherwise specified, to be protected with strong cross copper wire cross-bars. (See Fig. 22.)

FIG. 22

107. **Soil-pipe vent-pipe:—**

The soil-pipe outlet ventilating pipe to be of the same bore as the soil-pipe, and to be 17b. lead, and to enter the soil-pipe 1ft. above the branch pipe of the highest w.c. or slop closet.

OR. The soil-pipe ventilating pipe to be inches greater diameter than the soil-pipe, and of 8lb. lead, and to enter the soil-pipe 1ft. above the branch pipe of the highest w.c. or slop closet. (The area of the ventilating pipe should be as nearly as possible equal to the combined area of the soil-pipe and the vent-pipe—for instance, a 4in. soil-pipe and 3in. vent-pipe would require a 5in. ventilating pipe at top of soil-pipe. The extra size of vent-pipe would be necessary only when a large number of closets have to be served and the soil-pipe is of a great height—say, exceeding 80ft.)

108. **Caps:—**

Provide and fix to top of outlet ventilating pipe a copper wire domical cap.

109. **Fixing vent-pipe to roof:—**

Do all necessary cutting away and making good for ventilating pipe to pass through roof, secure pipe to roof with No. galvanised-iron stays, put 5lb. lead apron to pipe passing through roof and to galvanised-iron stays, the pipe and the stays to be soldered to aprons.

110. **Vent-pipe carried above chimneys or roof:—**

Provide for carrying up the outlet ventilating

pipe to soil-pipe, and waste from bath and sinks, by the side of chimney to a height of above (or below) the top of the chimney, and in the position required by the architect, the pipe to be bent outwards at the top, as shown in Fig. 23.

OR. The outlet ventilating pipe to be carried up ft. above the (state here whether eaves,

FIG. 23.

FIG. 24.

gutter, or ridge) of the roof, and to be fixed ft. distant from the dormer window or skylight.

111. **Size of anti-siphonage pipe to soil-pipe entering drain:—**

If the soil-pipe is not connected directly with an inspection chamber, and the drain into which it enters receives a discharge from a flushing tank or any large body of water, all the anti-siphonage pipes are to have a diameter in. greater than that shown on table (see Clause). This is necessary as a compensation for the loss of the air contained in the inspection chamber.

112. **Air inlet shaft:—**

Build where specified or shown on plan air-inlet shafts 12in. by 12in., with 9in. brick sides 2ft. 9in. high externally, and rendered internally with Portland cement. Cover ditto with a 2in. tooled York stone, and fix in one side a galvanised-iron barred grating, and paint ditto and connect shaft with inlet ventilating drain-pipe, which must be of in. diameter.

OR. Provide and fix at a in. 8lb. lead inlet ventilating pipe to a height of above floor of area, and connect at foot with bend of earthenware pipe, and put to ditto an open-balanced galvanised-iron fresh-air inlet cap, with mica cap of a pattern approved by architect. Protect pipe with casing. (When the inlet is an open space away from windows, the mica flap may be omitted. If these pipes are accessible from the road, or liable to be injured, they should be cased.)

113. *** Main anti-siphonage pipe to baths and sinks:—**

Provide and fix to the branch waste-pipe of the lowest bath or sink a 2in. lead anti-siphonage pipe, as specified in clause.

114. **† Vent-pipe to waste of baths and sinks:—**

Provide and fix to main waste from bath and sink, at a height of 1ft. above the branch waste of the highest bath or sink ‡ a in. vent-pipe.

115. **Anti-siphonage pipe to branch waste to pipes and sinks.**

§ Provide and fix to waste-pipe of baths and sinks anti-siphonage pipes of the same bore as the waste pipe, as specified in Clause , and connect with main vent at a height of 6in. above the top of the bath or sink.

OR. ¶ Provide and fix to waste-pipe of baths and sinks anti-siphonage pipes of the same bore as the waste-pipe, as specified in Clause , and carry through wall at a height of 6in. above the bath or sink, and put hinged brass flap to ditto.

116. **Vent-pipe to waste of flushing tank:—**

Put to waste from automatic flushing tank, about 12in. below the tank, a 2in. lead vent-pipe, and carry ditto to a height of 6in. above the top

* + This would apply to baths and sinks on different floors, fixed in tiers one above the other, or where the waste does not discharge into an open head.

‡ The size of the pipes must depend upon the number of baths and sinks which the waste-pipe has to serve.

§ This would apply to baths and sinks on different floors, fixed in tiers.

¶ This would apply to baths and sinks with waste discharging into open heads.

of the tank, and turn over ditto to right angles, and put cross copper wire in ditto.

OVERFLOW PIPES.

117. **Overflow pipes in sides of cisterns and lead-lined sinks*:—**

All overflow pipes from sides of cisterns and lead-lined sinks to be of at least double the sectional area of supply pipes, and the mouth of the pipe to be of such shape as to enable the water to run off as quickly as it enters, and to discharge with a fall of not less than 1 in 10 through wall into the open, and to be fixed with a light brass flap (see Clause); and in cases where the length of overflow exceeds ft., a proportionally increased area of overflow must be provided.

OR. Provide and fix in cistern and sink a lead stand-pipe overflow of at least double the sectional area of the supply pipe, and put trumpet-mouth to ditto, and fix over ditto a hollowed cover to ditto (see Fig. 24).

118. **Overflow carried through wall:—**

All overflow pipes and wastes from safes to be carried through external walls, and to project not less than 6in. beyond the face of the wall, and also 2in. beyond all cornices, sills, and other projections below the level of the overflow pipe.

119. **Ends of overflow pipes:—**

The ends of overflow and waste to safes to have light-hinged brass flaps, and the end of the pipe being cut at an angle of 60° with the lower sides. (When a back draught is not objectionable, these should be omitted, as they are liable to stick fast. Brass is specified as being less liable to stick than copper.)

120. **Overflow to sinks with plugged wastes:—**

Put to all sinks with plugged waste-pipes an overflow pipe (see Clause 102) carried through wall.

Lavatory overflows:—

See Lavatory Fittings in Part 4.

SERVICE PIPES.

121. **Size and weight of communication pipe:—**

The communication pipe to be of lead of the sizes and weights required by the Water Company, or, in case of private supply, of lead of not less than the following sizes and weights:—

3in.	5lb. per yard run.
4in.	6lb. "
5in.	7½lb. "
6in.	9lb. "
1in.	12lb. "
1½in.	16lb. "
1¾in.	21lb. "
2in.	28lb. "

122. **Depth of communication pipe below surface:—**

Underground communication pipes must be fixed at a depth of not less than 2ft. 6in. below the surface.

123. **Communication pipes inclosed in iron pipe:—**

Lead pipes laid underground or carried across open areas to be inclosed in galvanised iron pipes with red-lead joints. (This may rarely be required. The strength of the iron pipe must depend upon the object for which it is used. If the lead pipe requires to be protected from any heavy superincumbent weight, some precaution in addition to the iron pipe may be required.)

124. **Joints to communication pipe:—**

All lead communication pipes (Metropolitan Water Act, 1872) to have a wiped joint.

125. **Guard-box to stop-valve to communication pipe:—**

Provide and fix a guard-box to stop-valve outside the house.

126. **Size of service pipe to valve closets:—**

The lead service pipes to flushing rim valve w.c. apparatus to be of the following sizes:—

	Head of water.	Diam. of pipe.	Diam. of valve.
Under	3ft.	2½in.	2in.
"	5ft.	2in.	1½in.
"	10ft.	1½in.	1½in. or 1¼in.
"	15ft.	1¼in.	1¼in.
" and above 20ft.	1in.	1in.	

(If double closets are fixed on each floor, the

* It is impossible to specify the size, as this must depend upon the area of the service pipe and the pressure of the water. An oblong rectangular form is best fitted for the outlet of the overflow pipes from a cistern.

main service should be $\frac{3}{4}$ in. larger, and the branch pipes the same size as given above.)

127. Service pipes to wash down and other closets:—

Put lead supply pipe from water waste-preventer cistern to basin of wash-down closet, with flushing rim where direction of pipe is vertical and the head of water does not exceed 4ft. ($\frac{1}{2}$ in. is the most usual size, but some waste-water prevention cisterns require a larger and some a smaller pipe.)

OR. Put lead supply pipe from water waste-preventer cistern to basin of wash-down closet, with flushing rim where the direction of the pipe is at an angle of more than 30° and the head of water does not exceed 4ft. (The pipes should be increased in size in proportion to the inclination of the pipe, provided that the size is not greater than the waste water-preventer cistern and the w.c. basin require.)

OR. Put lead supply pipe from water waste-preventer cistern to basin of wash-down water-closet, with flushing rim if the head of water exceeds 4ft.

128. Size of pipes serving fittings on several floors:—

Provide and fix service pipes to sink, baths, &c., on different floors of the size given below, and put $\frac{3}{4}$ in. branch pipes to fittings on each floor. On ground floor, $\frac{3}{4}$ in. pipe; first floor, 1 in.; second floor, $1\frac{1}{2}$ in.; third floor, $1\frac{3}{4}$ in.; fourth and fifth floors, $1\frac{3}{4}$ in.; fifth and sixth floors, 2 in. This is necessary when the cistern has to supply fittings on each floor, in order that there may be a sufficient supply when several taps are open.

129. Direction of sewer pipe:—

All main and branch sewer pipes to be carried downwards in as direct a line as possible.

Lay on water with in. pipes to supply cistern. (The pipes to be of the following, say: High-pressure service, $\frac{3}{4}$ in.; low-pressure service, 1 in.)

Lay on water with in. pipes to water waste-preventer cistern. (High-pressure service, $\frac{3}{4}$ in.; low-pressure service, $\frac{1}{2}$ in.)

(N.B.—The water waste-preventer cistern should fill in not more than $\frac{1}{2}$ minute.)

130. Size of horizontal service pipe:—

If a horizontal length of service pipe is required between the cistern and its ascending portion, the horizontal pipe, together with its bends, and also a length of 6 in. of the vertical pipe, to be of an area 50 per cent. greater than

FIG. 25.

the vertical pipe, the outgo of cistern to be the same diameter as the horizontal pipe. (See Fig. 25.)

131. Position of unions to sewer pipe:—

The unions of sewer pipe to fittings to be placed in accessible positions.

TAPS AND OTHER FITTINGS.

132. Bosses to pipes:—

The bosses of pipes supplying sinks, lavatories, and other fittings, to be of sufficient length to allow of the cocks being easily screwed on.

ILFORD LOCAL BOARD OFFICES.

THE two designs selected by the assessor, Mr. G. T. Hine, for these offices are now on view. "Eureka," by Messrs. Clark and Hutchison, of 47, Strand, is placed first, and is a compact arrangement of offices. A central entrance, with committee-room on the left side and surveyor's offices on the other, with staircase hall at the back, forms the main block. The rate collector occupies the left wing next Oakfield-

road, and the sanitary office is behind it, with lobby for public. In the other corresponding wing we have a surveyor's second office and waiting-room behind. On the first floor, the board room is in front, facing the High-street, 40ft. by 20ft., and clerks' offices to left, with inquiry lobby. The other side of board room are the board's retiring and ante-rooms. The caretaker's house is on the west side. The design is balanced with hipped roofs, and clock tower in a Renaissance style. "Nab," by Messrs. Ben Woollard and Albert C. Bredon, of Finsbury-circus, gains the second prize. It is an artistically-drawn design in brick Renaissance. The collector and surveyors' offices are in front, approached by a wide corridor from behind, and committee and waiting rooms, plan, and sanitary offices in the rear; the staircase hall is spacious and well designed, leading to a board-room in front on the first floor, 35ft. by 20ft. in centre, with clerks' offices at the ends of corridor. The caretaker's rooms are on the second floor. The high tile roofs and gabled wings and the recessed board-room front make an architectural and pleasing elevation. The centre portion has pilasters between the mullioned windows of board-room. A pleasing coloured perspective is sent in.

CHIPS.

A painfully sudden death was witnessed in Manchester on Monday evening. Mr. William Kenyon Statham, aged sixty-three, builder and contractor, of 10, Brentwood, Eccles Old-road, Pendleton, was transacting business at 41, Corporation-street, in company with a Mr. Joseph Tiverton, of Ardwick, when he was heard to say, "I am going," and immediately expired. The deceased had been in ill-health for some time, and was medically attended a week ago.

At Mold, on Tuesday, Major-General Crozier, Local Government Board inspector, conducted an official inquiry as to the proposed sewerage scheme for the town of Mold, which has been estimated to cost £4,500. Mr. Radford, civil engineer, Nottingham, presented plans of the proposed scheme to the inspector, and no opposition was forthcoming. The inspector intimated that the necessity of a sewerage scheme went without saying.

The Bishop of Lichfield has appointed Mr. J. R. Veall, architect, of Wolverhampton, a diocesan surveyor under the Ecclesiastical Dilapidations Act, 1872.

The Prince of Wales, on Saturday, laid the foundation-stone of the new Clarence wing of St. Mary's Hospital, Paddington. Towards the £100,000 required to complete the extension, £48,000 has been obtained. One part of the buildings will be devoted to the purposes of a Nurses' Home, and another block will constitute the new out-patients' department. A third block will contain wards for the treatment of special diseases. Lying-in wards, a new administrative department, and accommodation for resident medical officers and students, will be provided.

Mr. S. M. Copeman and Mr. Rienzi Walton (Local Government Board inspectors) held an inquiry at Stratford-on-Avon last week relative to the application of the corporation for sanction to borrow an additional £4,000 to carry out extensions of the waterworks, £2,500 for the erection of an infectious diseases hospital, £370 for a fire station, and £480 in connection with an exchange of land for a public recreation ground.

The church of St. James's, Hill Top, West Bromwich, after undergoing a thorough cleaning, alteration of the interior, the removal of the organ and choir from the west gallery, the formation of a chancel, and being redecorated throughout, was reopened last week by the Bishop of Lichfield. The outlay has been £700.

At the last meeting of the Highway Board for Con Dover, the chairman said that at previous meetings of the board their newly-appointed surveyor, a Mr. E. H. Johnson, had been requested to find a bondsman for £300 and produce his testimonials from the Norfolk County Council. He had not yet done so, and the Finance Committee, who had gone into the matter fully, had passed the following resolution, which they recommended the board to adopt:—"That Mr. Johnson, not having complied with the conditions upon which he was appointed, this committee recommends that his services be dispensed with from this day, and that advertisements be immediately inserted in the local papers for his successor." A discussion followed, in which it was asserted that Mr. Johnson had been repeatedly asked to find security for the sum stated in the resolution, and also to produce his testimonials. He had not done so, and the committee had no alternative but to submit the foregoing resolution to the board. The resolution was unanimously adopted.

Building Intelligence.

AINSWORTH, LANC.—A new Methodist New Connexion chapel has been opened at Ainsworth. The walls are built of local stone, faced with Yorkshire parpinto, and dressings of Halifax stone. Internally the upper portion of the walls is finished in plaster, and the chapel has a waggon-headed ceiling, with moulded beams and cornices, the lower portions of the principals being exposed to view and resting on stone corbels. The organ-chamber and choir-stalls are separated from the vestries by panelled glass partitions, and the vestries and organ-chamber can be thrown into one large organ gallery for use on special occasions. The seats, dado, rostrum, and organ gallery front are of pitch-pine varnished. The church is lighted, and the premises are heated by hot water. The chapel affords accommodation for 200 persons. The works have been carried out from the designs of Mr. John Wynne, F.R.I.B.A., architect, of Manchester. Messrs. Robert Brooks and Sons, of Ainsworth, have been the contractors for the stonemasons' work; and Messrs. Yonng, Tinker, and Young, of Manchester, have been the contractors for the whole of the remaining trades, and have executed the joiners' work.

VAUXHALL, S.W.—A common lodging-house has just been erected at the cost of Lord Rowton in Bond-street, Vauxhall, from plans by Mr. Beeston. Sleeping and living accommodation is provided for 462 men. The building, which is of red and stock bricks relieved with Newbiggin stone of the same colour, laid in cement, is five stories in height. The floors are of concrete with steel joists, and the staircases of concrete, so as to render it as nearly as practicable fire-proof. It covers an area of 150ft. of frontage, by a depth of 105ft., and includes a yard, extending the whole length of the building, for out-of-door exercise. The walls of the passages and staircases are of white glazed bricks. Two dining-rooms, seated for 192 persons, occupy nearly the whole length of the building at the back, looking on the platform of Vauxhall Station. The walls of all the living-rooms are built dado high in chocolate and cream glazed brickwork with the wall above tinted a shade of terracotta. The sleeping apartments are heated by hot water pipes.

Engineering Notes.

WEST INDIA DOCK.—A new lock entrance is being made to the West India Dock, and will be opened in about twelve months' time. The contractors, Messrs. Lucas and Aird, commenced operations in September last. The lock, which will open into the Blackwall Basin, will be 430ft. in length, 60ft. wide, and 30ft. in depth, and the cuts leading from the basin to the Import and Export Docks will be increased in width and depth to the same dimensions. Pumping machinery will be provided for keeping up the depth of water to 25ft. The quays will be widened and be made suitable for movable cranes. The total outlay will be about £200,000.

Mr. Percy Wood has taken a cast of the late Sir Richard Owen's head, and he has been commissioned to execute a statue.

The time for depositing in the Private Bill Office of the House of Commons all Private Bills which will be promoted in the ensuing session of Parliament expired on Tuesday, when only 183 bills had been lodged. This number is the lowest on record during the last 20 years, the nearest approach to it being in 1887, when only 193 bills were deposited. Compared with last year, when 219 bills were lodged, the decrease is 36. Of the total number now deposited 144 relate to England and Wales, 25 to Scotland, and 14 to Ireland.

Messrs. Robert Boyle and Son, Limited, ventilating engineers, London and Glasgow, have been awarded a gold medal, the highest award at the International Exhibition, Kimberly, South Africa, for their latest improved patent self-acting air-pump ventilators and air inlets. The exhibition is ventilated throughout with air-pump ventilators. Messrs. Boyle's ventilating appliances are employed in most of the public buildings in South Africa, and are specified by the Imperial and Colonial Governments. Mr. Robert Boyle recently made a tour through South Africa, and agencies are established in the different colonies.

COMPETITIONS.

THE LONDON BOARD SCHOOL AT BROMLEY.—At the last meeting of the London School Board a long and animated discussion arose on the report of the Works Committee (summarised in our last issue, p. 860) as to the competition conditions for the school to be erected, from outside architects' plans, at Priory-grove, Bromley. An amendment to reject the report and continue the present plan of having schools planned and superintended by the permanent staff of the board received 20 votes to 20 votes against, and was lost by the chairman's casting vote. In a like manner (21 voting for and against) an amendment stating that "the board do not bind themselves to employ the successful architect in the erection of the school," was also defeated by the chairman's casting vote. Eventually it was decided to invite designs for a school for 1,200 instead of 800 children, and to add the words: "That the designs be accompanied by general specifications and reports showing system to be recommended for heating, ventilation, and drainage, also estimate of probable cost." To the recommendation "That three premiums of £150, £100, and £50 be awarded in the discretion of the assessor" was added the words "and that the sets of plans for which the premiums shall be awarded shall be the property of the board." As thus amended the committee's recommendations were finally adopted.

ILFORD.—The chosen design for the new public buildings at Ilford, comprising local board offices and a fire station, is by Messrs. Clark and Hutchinson, architects, 47, Strand, who are awarded the first premium of 50 guineas. The second prize of 25 guineas has been given to Messrs. Ben Woollard and Albert C. Breden, of Finsbury-circus. A review of the premiated designs appears on the preceding page. Mr. G. T. Hine was the professional referee.

RADCLIFFE, LANCs.—In response to an offer of premiums of £30, £20, and £10 respectively for the three most suitable plans for a technical school, the Radcliffe local board have received 50 sets of designs. They will be adjudicated upon by the board, assisted by an architect as assessor.

WALSALL BOARD SCHOOLS.—At the last meeting of the Walsall School Board, the plans of Messrs. Bailey and McConnal were adopted for the schools proposed to be erected at the Birch-hills. Mr. H. H. McConnal, A.R.I.B.A., of Walsall, is to be congratulated, for he has recently won the first premium for the Town Hall, the first premium for the Hilliary-street board schools, and the second premium for the public baths in the same town. A review of the plans for the Town Hall and baths appears elsewhere.

ARCHÆOLOGICAL.

NEWBATTLE ABBEY.—An important discovery has been made at Newbattle Abbey, Dalkeith, the seat of the Marquis of Lothian. Some workmen employed near the abbey house digging pits struck upon a piece of solid masonry, and the Marquis of Lothian gave orders to have the ground completely taken away from about the stonework, bringing to view the foundation of the north transept and side chancels of the old abbey. In 1878 extensive excavations were carried out near the same place, when the nave, aisles, and south transept were found, and by the present discovery the ground plan of the old abbey has been almost completed. All the foundations have been filled up again, and marked off with gravel surfaces. The north transept is 46ft. wide inside between the east and west walls, including the side chapels. From the inside of the north wall to the north aisle is 30ft. 9in., and the length of the main building from the great western door to the east end at the chancel is 293ft. 3in., whilst the width across the nave and aisles is 57ft. 1½in. The width from north to south transept, including the crossing, is 122ft. Newbattle Abbey was founded by the Cistercian Monks in 1140. Part of the old boundary wall near the river Esk has also been excavated and marked out. The work of excavation has been carried out under the superintendence of Mr. John Ramsay, clerk of works.

The Newbury Corporation resolved on Tuesday to apply to the Local Government Board for authority to borrow £30,350 to carry out a main drainage scheme in that borough, the engineer engaged being Mr. Austie.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

BIRMINGHAM ARCHITECTURAL ASSOCIATION.—A meeting of the above association was held at the Birmingham and Midland Institute on Tuesday evening last, under the presidency of Mr. W. Hale, F.R.I.B.A. The formal business, which included the election of twelve new members, was followed by a paper on Rouen Cathedral, read by Mr. J. A. Grew, who, after giving a short description of the cathedral, proceeded to discuss closely the beauties of the exterior. Referring to the west façade, he pointed out that though almost entirely covered with varied and intricate ornament, the main lines and masses are so disposed as to lose none of their importance, and that as the visitor approaches the cathedral from the narrow street leading to the Place at its western end, it is not the ornament, but the finely-proportioned mass and imposing lines of construction which first attract his attention, and that though in places the work has been damaged in the lapse of time, yet new beauties have been added by the same cause, and the façade is still so nearly perfect in its beauty as to be beyond criticism. Having drawn attention to many special points of interest, Mr. Grew brought a very interesting paper to a close. A vote of thanks to Mr. Grew was proposed by Mr. Doubleday and supported by Mr. H. R. Lloyd, Mr. W. Hale, Mr. A. Harrison, and others, and a brief response from Mr. Grew terminated the proceedings.

EDINBURGH ARCHITECTURAL ASSOCIATION.—At the last meeting of this association, Mr. T. Crichton Fulton, Glasgow, delivered a lecture on the "Electric-Lighting of Large Buildings." He explained in a popular manner the principles underlying the modern methods of generating electricity in large quantities by dynamical means, and showed how the essential conditions were applied in the construction of continuous-current dynamos. In speaking of the distribution of electricity, the lecturer described the circuit, and explained the use of switches. He also showed how loss was prevented and dangers averted by the proper insulation of all conductors, &c., and by the use of safety fuses; and gave point to his remarks by referring to a fire which occurred in London only the other day by the overheating of one of the wires. Mr. Fulton next referred to the work of the current, and explained how both arc and incandescent lamps are made and arranged, and how they work. In applying his remarks to various kinds of installations, he took occasion to emphasise how important it was that the machinery, upon which everything depends, should have plenty of space, light, and air, and should be kept scrupulously clean. He next went on to describe as typical installations a country house with water-power available, a factory in town with boiler-power and a steam engine, and a large church, with a gas-engine for its prime mover. In concluding, he dwelt on the propriety of having all work properly designed from the beginning, and thoroughly inspected and tested whilst in progress.

LEEDS AND YORKSHIRE ARCHITECTURAL SOCIETY.—The members of this society held a "social evening" on Monday night in the Queen's Hotel, Leeds. There was a good attendance of members, to whom a capital programme of music was presented, arranged by Mr. T. H. Churton. At the opening of the concert Mr. G. B. Bulmer, the president, presented the silver medal of the society to Mr. Lindsay Grant for his drawings of ancient buildings.

At a meeting held in Leeds on Tuesday to consider what form the memorial to the late Canon Jackson should take, it was decided that the memorial take the form of a new wing for the Convalescent Home at Cookridge, to be called the "Edward Jackson Wing," the accommodation being for women and children. The total amount of subscriptions already promised is over £1,300.

A town clock for Gateshead, which has been erected in front of the town hall, was presented to the inhabitants of the borough on Tuesday by the mayor. The clock-tower is an exact *fac-simile* of the one placed at the end of Vauxhall Bridge-road, near Victoria-station, S.W., by the vestry of St. George's, Hanover-square. The tower is 25ft. high, and the total weight five tons. There are four dials, each 2ft. 6in. in diameter, made of copper figures, and glazed with opal glass for illumination. Messrs. Gillett and Johnson, of Croydon, supplied the clock and tower.

Correspondence.

WESTMINSTER ABBEY.

To the Editor of the BUILDING NEWS.

SIR,—Your correspondent "M." ought to blame the fifteenth-century architect for robbing us of the "original west doorway," not "the Wren"; and, at the same time, he coolly suggests that Mr. Pearson should rob us of Wren's work by rectifying the towers. I have more than once heard the remark that Wren added to these towers with "considerable success, considering that he hated Gothic," and this success, to my mind, is due to his working on his own lines. The upper windows of the towers show, it is said, that he had not caught the spirit of the Perpendicular work. Perhaps he did not want to catch the spirit. Why should he, living in the eighteenth century, try to design as they did in the fifteenth?

Personally I like these towers very much, the better for being able to say when they were added to by simply looking at them, instead of being puzzled as to what is genuine Perpendicular in the west front, as a future generation will be puzzled as to what is nineteenth-century work of the north transept.—I am, &c., C. F. M.

SIR,—Most of your readers must have noticed with satisfaction the spirit of tolerance and good taste which has uniformly characterised your remarks on subjects which are necessarily nearly related to theology. It is, therefore, with the greater regret that I see in your correspondence column a letter which cannot but outrage the feelings of a large number of individuals, and which is totally foreign to the purposes of a secular journal.

The communication from your correspondent who signs himself "M." is, so far as his architectural remarks go, quite unexceptionable, though we should be strongly inclined to doubt that the absence of lateral chapels was due to any comparative immunity from so-called "superstition." As a matter of fact, the existence of side chapels and side altars is abundantly manifest in the Abbey as now existing.

But when your correspondent proceeds to speak of the very fine Madonna and Child which adorns the entrance to the north transept, he speedily makes himself ridiculous. According to his reasoning, so far as we can make it out, a statue of the "old fisherman," as he is pleased to term St. Peter, would, regarded as a work of art, have been respectable, whereas a representation of Our Lord and His Mother is distinctly not so. A precious distinction indeed! We have yet to learn that Raphael's "Madonna" and Murillo's "Immaculate Conception" are lacking in respectability.

Seriously, Mr. Editor, is it not rather late in the day for this Puritanical homily, and are not your correspondent and the kindred spirit whose sacrilegious outrage he approves worthy successors of the iconoclasts who dissipated in a few years untold treasures of art, the fruit of ten centuries of faith and love?

With apologies for so trespassing on your space,
—I am, &c., ICON.
December 16.

VICARIOUS DESIGN.

SIR,—In the current number of the BUILDING NEWS you lead with an article on "Vicarious Design," on which, if you can spare the space, I should like to make a few remarks.

The writer says "when he" (the architect) "draws with his own hand the full-size profile of moulding on stone or wood" (why not on paper?) "we get pretty near to the directness of the sculptor's chisel or the painters' brush. The artist's ideal is actually brought to the material by this means, but the case is very different in practice. The eighth of an inch scale drawing is interpreted by the foreman or clerk of works; he enlarges it to a full-size drawing, and this, again, is handed to the mason or joiner who executes the work. The original is nearly lost in the translation; the moulding is quite another profile to that which the architect drew" (?), "or it is so distorted by bad drawing in the curves and members that he feels disgusted with it when he sees it."

And so he ought to feel disgusted, but with himself for shirking his work, and not doing that which he is paid to do; and, as a member of the

architectural profession, I cannot let this statement pass unchallenged.

I hope that none of the "laity" will read that article, or they will think that architects earn their commission very easily.

Fancy an architect drawing the eighth scale plans and getting out the specification and quantities, and then thinking he had finished his work! Why, he would only then have got ready to begin the most important part of it.

I have been in a few architects' offices, and not all small ones either, where I find the case to be very different in practice, for, as the majority of your readers know, it is usual for the architect or the assistant who has drawn or superintended the drawing of the plans of the particular building to draw with his own hand, not only all full-size details where required, but also all details of an intermediate scale—i.e., one inch to the foot, or so; the full-size drawings are handed to the contractor, whose yard foreman draws it out on wood for the carpenters, or has it cut out in zinc for the masons, or has a mould made if for plasterers, and so forth.

Such, Mr. Writer, is the case in practice, for how can an architect be said to draw the profile of a moulding to eighth scale? He may indicate that a string or cornice is going in at such a place, but that is all. I think, Sir, you will find that, although it be very pretty to write of art culture and art craftsmanship, yet to write of any art it is necessary to be acquainted with the *modus operandi* thereof, and I maintain that "Vicarious Design" in the sense of your article does not exist.

In my own case I must admit that I do draw some of the inch scale and full-size details, but they are all overlooked by the architect, and corrected and amended if necessary.—I am, &c.,
CLERK OF WORKS.

VENTILATION.

SIR,—I have perused in your latest issue the paper on ventilation read by Captain MacIlwaine at the Royal United Service Institution and Messrs. Robert Boyle's remarks thereon. The subject, especially at the present time, is, in view of the anticipated visitation of cholera, undoubtedly one of the highest importance, and too much attention cannot be drawn to it, as the health of the people and their capacity for warding off disease depend so much upon the proper ventilation of the public buildings they frequent, and also of their homes, though the efficient ventilation of drains, sewers, and soil-pipes is of equal importance. Not a moment should be lost in having everything done that is possible in this direction, so that we may be able to meet the advance of the fell scourge with comparative equanimity and safety. I have always taken the deepest interest in ventilation, and indeed have made the subject a special study practically as well as theoretically, and my experience has taught me that there is all the difference in the world between the one and the other, and that an ounce of practice is worth more than a ton of theory, however elaborately the theory may be worked out and to the satisfaction of the theorist. The authority quoted by Captain MacIlwaine for the statement that for the proper ventilation of a building 150 cubic feet of air per hour per head is required, and which is endorsed by Messrs. Boyle, is certainly much nearer the mark than another authority quoted, who fixes 3,000 cubic feet as the quantity that should be supplied: and yet both are in a certain sense right. The calculation of one is evidently based on the supposition that a system of ventilation is employed which prevents the products of respiration and exhalations from the body from accumulating, and draws them off as fast as they are generated, which Messrs. Boyle claim their system accomplishes. The other calculation is doubtless based on the assumption that plain open pipes, or other such contrivances, are employed, which do not at once and continuously withdraw the foul air as it is generated, but permit cold down draughts, which experience proves they almost invariably do, and which, as Captain MacIlwaine very correctly points out, press back the hot, vitiated air, precipitating the impurities and poisonous matter to be breathed over again. The 3,000 cubic feet per hour is simply, as I read it and understood it, employed for the purpose of diluting the air respired by an adult in that time—viz., 15 cubic feet, to reduce the excess of CO₂ thus created in the air to a healthy standard. This, however, is not ventilation, but merely

dilution—two very different things—by mixing a given quantity of foul air with a given quantity of fresh, so as to reduce the CO₂ contained in it to a fixed point. It is obvious that if the excess CO₂ is immediately removed as soon as formed by any method of ventilation, and a supply of fresh air admitted at a proper level, there will be no excess of CO₂ left in the air requiring dilution to any such extent, and therefore the 3000 cubic feet to be employed for that purpose would be quite unnecessary. I am at one with Captain MacIlwaine's authority and Messrs. Boyle when they state that with a proper system of ventilation 150 to 200 cubic feet per hour per head are sufficient for all ordinary requirements. In a large, crowded building, say Exeter Hall, if 3,000 cubic feet of air, or anything like that quantity, were provided for each person per hour, the draught would be so great that it would be impossible to occupy the building except at the greatest risk to health and total destruction to comfort. The remedy would be worse than the evil it was intended to cure. That is the objection to mechanical ventilation, which usually drives air into a building at such a high velocity that disagreeable draughts are experienced in the immediate vicinity of the inlets, whilst other parts of the buildings are left stuffy and unventilated, as the incoming columns of air usually travel in a direct line to the nearest outlet, and there make their escape. This is partly the cause of the complaints we so frequently read about in the daily papers respecting the failure of the mechanical ventilation at the new London Law Courts, and, so far as my experience goes, is a fair sample of mechanical ventilation generally, which is not only costly to install and maintain, but is unreliable and perpetually going wrong, either through the want of proper attention (which is seldom given) or owing to the mechanism breaking down or getting out of order. At its best, this system can only claim to ventilate a building when it is in operation—that is, for the few hours at a time that the place may be occupied, and for the rest of the time the ventilation is nil, when stuffiness and stagnation reign supreme. A method of artificial ventilation more objectionable still and dangerous to health is where the air-supply is forced through a water-spray, as it usually gets saturated with moisture to such an extent that if a handkerchief is held above the mouth of the inlets it may be found in a few minutes to be soaking wet. It can easily be imagined what the effect of this would be in a heated atmosphere, when the air would become steamy and oppressive, and more like a vapour bath than anything else. All forms of ventilation which depend for their action or efficiency on water are open to the fatal objection that in winter, when the water-pipes are frozen, they are rendered inoperative, and the ventilation is brought to a standstill.

My experience is that an automatic or natural system of ventilation is, in the long run, the most reliable and satisfactory, providing, of course, that properly-constructed ventilators are employed, and that they are skillfully applied by a competent engineer. I am quite aware that there are many very indifferent ventilators in existence, and also incompetent persons who style themselves ventilating engineers, and that automatic ventilation under such auspices might and probably would prove a failure; but, then, such ventilators and such engineers need not be employed.

One great advantage of the automatic system over a mechanical or artificial one is that it is always at work day and night, though some people have the idea—a mistaken one—that it is only when there is a breeze that this method of ventilation acts. Science, however, proves that there is not a moment of time but when there is a movement of the air, which is never stagnant, though it may seemingly be so, and that this movement properly utilised is sufficient at all times to change the air in a building and secure ventilation. I agree with Captain MacIlwaine, that it is wrong in principle and contrary to the laws of nature to attempt to withdraw the vitiated air from a building at the floor level, and no one having the slightest practical or scientific knowledge of the subject, or of the natural laws which govern ventilation, would ever advocate such a method. With respect to the so-called experiments with ventilators carried out about fourteen years ago by the Sanitary Institute, and known as the "Kew farce," it may be remembered by some of your readers that these experiments were instituted to determine the

relative values of three or four cowl which were shown at a sanitary exhibition, and which resulted in the fiasco described by the *Times*, which not only condemned the tests as worthless and proving nothing, but warned the Institute that if it desired to gain the confidence of the public it must be careful not to commit any more such blunders in the future. The extraordinary proceedings in question and conclusions arrived at, that an open pipe was the best and most reliable ventilator, so entirely contrary to all practical experience past and present, certainly tended at the time to injure the prospects of the Sanitary Institute, then newly formed, and to retard its advancement to the position it aimed at, to be recognised as an authority on sanitary questions. Most people, however, know from painful experience that it is no more conducive to health or comfort to sit under a down draught of cold air from an open pipe than it is to sit under a cold douche with the temperature below freezing-point. Such doctrines might, perhaps, have been accepted in the middle ages, but not now; and, as I have heard it expressed, the attempt to foist such ideas on the public is not only an impertinence, but an insult to the intelligence of the nineteenth century. Sir Douglas Galton, President of the Sanitary Institute, in condemning the open pipe as a reliable exhaust ventilator, only states the experience of all who have any practical knowledge of the ventilation of buildings—a very different thing from mere dilettante experiments carried out by three or four irresponsible individuals, themselves inventors of ventilating and sanitary appliances, for the purpose of deciding on the merits and passing judgment on the ventilating appliances of rival inventors and sanitary engineers. Certainly the taste displayed in the selection of such a jury might to some seem questionable, and it would perhaps have been wiser and inspired greater confidence in the public mind if the professional interests of the gentlemen who composed it had been different from those whose appliances they were judging, though in saying this it must not be inferred that I in any way question the *bona fides* of the transaction; but of what possible value to the public could these experiments be at the present day, even supposing they had proved anything at the time, seeing that the forms of the ventilators that were tested are now practically as extinct as the dodo?—I am, &c.,

CHARLES HOUGHTON, C.E.

London, December, 1892.

PLUMBING.

SIR,—I have to thank Mr. Baker for his kind reception of what he calls my criticisms, and I accept his invitation to continue them.

Mr. Baker agrees with me in the desirability of using small pipes, but suggests a few objections. I will take these objections seriatim, and shall, I think, be able to show them to be only imaginary. A bright, well-polished pipe may not be everything, but it is far and away the most important; if the inside of all the pipes be kept clean and bright, and this cannot be done without a free circuit of air, it follows that no objectionable matter can remain in them, and consequently there is nothing to evolve noxious vapours; the only point then left to look to is the exclusion from the drain of gas from the sewer.

As to siphonage, a 3in. soil-pipe will not siphon more readily than a 4in.; indeed, if one of the improved wash-down closets, which have 3½in. to 4in. outgo, be used, there is less chance of danger with a 3in. than with a 4in. pipe; besides which it is perfectly easy to render siphonage absolutely impossible, even without the use of "anti-siphonage" vent pipes.

I now come to his second objection. A small waste, with a perfectly clean water-way, unobstructed by any trap, and consequently running full bore, will allow more water to pass than a larger waste obstructed by a trap which acts as a considerable check on the discharge. A 1in. waste will discharge, under ordinary circumstances, about 24gal. per minute, and will therefore empty a lavatory in a few seconds, and a 1½in. waste will discharge about 70gal. per minute, which will empty a full bath in less than half a minute. An ordinary bath is fitted at the outgo with a brass grate pierced with six holes ½in. diameter, the total area of which amounts to 2½ circular inches, while a 1½in. pipe contains 2½ circular inches. These sizes are practically the same, and as the discharging capability of a pipe depends upon its smallest area, the discharge will not be increased by using a larger pipe,

while the efficiency of the flush is destroyed, as the larger pipe will not run full bore.

The illegal "regulations" of the vestries do not count when we are considering the best mode of sanitation, although, undoubtedly, we have sometimes in practice to do as they require, only to have to rectify their blunders later on.

I heartily endorse Mr. Baker's advice not to hastily adopt untested theories; but I would also add a strong word against the use of commonly accepted but obsolete methods (upon the use of which vestries endeavour to insist) upon the assumption that they are proved facts, whereas they are in many cases not only mere theories, but theories that, if carefully examined, would be proved fallacious. I refer to one in particular—the idea that the air will circulate in the pipes in a certain direction simply because a few arrows are marked on the drawing to show what way the air ought to flow.

In reply to "F. S. I.," in the case he mentions there is no necessity for any extraordinary precautions. The waste pipe should discharge over the R. W. head, and not be carried down into it; the R. W. pipe should, of course, be disconnected, with a shoe at the foot; the air then passes freely through the pipes, and there is no chance of either becoming foul. Brass flaps are not to be recommended any more than traps, as they close the end of the waste and prevent the free circulation through the pipe of air that is so necessary to secure a perfectly clean and sweet pipe. I can assure "F. S. I." that the plan I recommend I myself adopt with perfect success; but if he has any doubt, he can employ a wide R. W. head and discharge the waste into one end and connect the down pipe from the other—but let him see that the head has a good and clean fall from the waste to the down pipe.—I am, &c.,

BERNARD DICKSEE.

35, Queen Victoria-street, Dec. 19.

Intercommunication.

QUESTIONS.

[10915.]—**Leaky Roof.**—Can I make a good job if I cover a small slate roof of flat pitch with lead or zinc, the lead to lie directly on the slates without boarding? It is important that the slates be not removed? If possible, rolls should be dispensed with.—**PLUMBER.**

[10916.]—**Strains in Girders.**—Will some reader kindly refer me to some good book for the determination of strains in girders and bridges, &c., also say whom I may be likely to find to coach me (I mean whether school-master or specialist in any particular branch of study), as I am living in a town where it is taken up by nobody in class!—**STUDENT.**

[10917.]—**Warming by Steam.**—Can the upper part of a house be warmed from the ordinary kitchen boiler on the ground-floor by steam, hot water, &c.? Has it been done, and, if so, where? Is there a small book on the subject?—**THOS. SOFTLEY.**

[10918.]—**Levelling.**—In levelling along a road, if my B.M., to which I have to reduce my levels, is half-way along that road, and suppose I am told I am to pick up my B.M. as I worked my way along the road, and not to start on my B.M. and work up to the place I am to start my section from? How, in the former case, am I to obtain my first reduced level from that B.M.? If I have a section to make half a mile away from my B.M., do I start on my B.M. and work up by B.S.'s and F.S.'s, never minding intermediates, until I arrive at the starting place? Without using the prismoidal formulæ or tables, how would I compute the contents of a cutting, &c.? What scales would you prefer to use to plot a section, if you were at liberty to use any one you liked?—**SECTIONS.**

The president and council of the Royal Academy have elected Mr. Leonard Watts, of South Hampstead, to the Landseer Scholarship, value £40, tenable for two years.

At a meeting of the Gateshead School Board, held in their offices West-street, Gateshead, it was resolved that they appoint Mr. Geo. Bell, quantity surveyor, Collingwood-street, Newcastle, as independent quantity surveyor for their proposed new schools at Shipcote to accommodate 1,000 children, the cost not to exceed £7,000. Mr. Stephen Piper, M.S.A., of Newcastle, is the architect, his designs having been selected in competition.

At the Central Criminal Court on Tuesday, Thomas Dooby, formerly secretary of a branch of the Navvies' and Bricklayers' Union was indicted for publishing a defamatory libel concerning Arthur Humphry, secretary of the union. Defendant expressed his regret, and said the charges were unfounded. The Recorder ordered defendant to find a surety for £25, and to enter into recognisance for the same amount to come up for judgment if called upon within twelve months, and warned him that if the offence was repeated, he would be sent to prison.

Legal.

A TRIBUNAL OF ARBITRATION.

THE London Chamber of Commerce, acting with the Corporation of the City of London, have now established a London Chamber of Arbitration. This is in working order, with plenty of business waiting to be done. It is, of course, founded upon the same principle of the assent of the parties as gives jurisdiction to every case of private arbitration. This submission, signed by the disputants, is the basis of its power, and this forms an irrevocable contract between them to be bound by the award as a final settlement of their dispute without possibility of any appeal. But the importance of the step taken in providing this tribunal of arbitration lies practically in the fact that it brings what was formerly a matter of purely private arrangement in each special trade or business into full public view. The result should be, and doubtless will be, to encourage the method of settling disputes by arbitration, to the discouragement of litigation, with all its delay, costliness, and uncertainty. The London Chamber of Arbitration have issued rules, forms, and fees for the conduct of business. These are very plainly dealt with and explained in "A Guide to the Law and Practice of the London Chamber of Arbitration," written by Messrs. Shearman and Haycraft, barristers-at-law (London: Effingham Wilson and Co., price 2s. 6d.). The book at the same time explains very well and clearly the law as to arbitration and the processes of the High Court in regard to references, and to enforcing awards since the Act of 1889, which is given in full; the whole forming a handy and useful manual.

This general tribunal is primarily intended for the decision of commercial cases; and upon the roll of men who have consented to act as arbitrators will be found the best representatives of every kind of trade, and of every branch of business. The great thing wanting in an arbitration is that the disputants should have the most complete confidence in the court, whose award is to be final. It is here that judges and juries have latterly failed to satisfy mercantile men; and it is for that reason mainly that business cases have gradually left the Law Courts to be disposed of by private arbitration. But though the new tribunal is primarily intended for commercial matters, it can be used for every possible dispute. Almost every contract made in the building trades contains a clause as to arbitration, and though usually the architect is appointed sole arbitrator, there are many cases in which this is left open. In these matters it would be perfectly possible to use the London Chamber of Arbitration, if the parties agreed so to do. The influence of the new tribunal will soon be felt in the way of simplifying and cheapening all arbitration proceedings, including those before surveyors. Here we are to have no meddlers, fuss, or formality; all the forms used are short, clear, and to the point. The fees are fixed low, being one guinea, as an office fee, including attendance of Registrar; and two guineas for the first hour, with one guinea per hour after that for each arbitrator or umpire, with no further fees in the award. The legal assessor is expensive, being put at £5 5s. for his attendance; but he can, and doubtless will, often be dispensed with, so that it will be perfectly possible to get a short dispute entered, heard, and decided finally by a single arbitrator for three guineas altogether.

FRED. WETHERFIELD, Solicitor.

1, Gresham Buildings, Guildhall, E.C.

NOTE.—All questions for reply in this column must be headed "BUILDING NEWS," and must reach my offices, as above, by Tuesday morning to insure answer same week.

CONSTANT READER.—AGREEMENT.—NOTICE TO QUIT.—(1) The notice is sufficient under the agreement, and will expire on 28th March next. (2) He must make good all damages of the kind named. (3) Yes, if he stayed and paid rent it would be under the terms of the agreement as far as applicable to a yearly tenancy. (4) No, it is not essential that you should accept his notice to quit.

The Stourbridge Commissioners decided, at a private meeting on Saturday, to purchase the local gasworks from the company now owning the property. A loan of upwards of £120,000 has been negotiated for the purpose of carrying out the purchase.

LEGAL INTELLIGENCE.

IN RE W. BAKER.—At the Worcester County Court on Saturday, before Sir Richard Harington, William Baker, formerly carrying on business at Colwall as a builder, contractor, and farmer, who filed his petition on November 13, 1891, applied for his discharge in bankruptcy. The Official Receiver reported that a dividend of 5s. 4d. in the pound had been paid upon liabilities of £779 9s. 3d., that the failure had been brought about by a number of building speculations and insufficient capital. He further reported that he had within three months of his bankruptcy given an undue preference to his father-in-law.—The judge suspended the discharge for two years.

CHARGE AGAINST A BUILDER'S CLERK.—William Light, 42, a managing clerk, of Wandsworth-bridge-road, was charged at the Marylebone Police-court, on the 15th inst., with stealing £42, the money of William Seaman, builder, of 132, Ashmore-road, St. Peter's-park. According to the evidence, the prisoner was managing clerk in the prosecutor's service for two and a-half years, and was discharged in October last for neglecting his duties. Since then the books had been overhauled, and it had been discovered that cheques had been drawn for wages representing a larger amount than the sums actually paid.—Prisoner was committed for trial.

LOCAL BOARD SURVEYOR AND BUILDER.—In the Isle of Wight Bankruptcy Court, on Friday, the public examination took place of Joseph Chinchin, of East Cowes, builder and contractor, and surveyor to the East Cowes Local Board. Gross liabilities £2,333 7s. 9d.; expected to rank, £895 9s. 4d.; available assets, £696 11s.; deficiency, £198 18s. 4d. The debtor said he commenced business in 1875, having £25 capital. He entered into a contract with the Government last April twelvemonth to carry out for three years all necessary work at the Barracks at Parkhurst and Cowes. He took the work at 24 per cent. off the scheduled prices, 1½ per cent. lower than the previous contractor had tendered. He had lost on the contract. Being surveyor to the local board, he was unable to give personal attention to the contract work, and had to trust to men who were not scholars enough to look after his interests, the result being that wages were too high. The debtor passed his public examination.

IN RE W. SARGEANT, CLACTON-ON-SEA.—Wallace Sargeant, builder and contractor, of Clacton-on-Sea, whose statement shows unsecured liabilities £3,365 11s. 8d., with a deficiency of £2,667 5s. 10d., came up for his public examination on Friday. Debtor said that he was a practical carpenter and joiner, and eight years ago he went into business at Clacton as a builder, with a capital of £50. Since November, 1891, he had contracted nearly all his present debts, which were £4,700 (gross), the deficiency being £2,667. He expected to be able to pay from contracts in hand, on most of which, however, he made losses.—The examination was adjourned for the debtor to file an account showing how his deficiency has arisen.

CLAIM AND COUNTER-CLAIM.—PILE V. BOYERS.—This was an action brought by Mr. Thomas P. Pile, of the city of Dublin, builder, to recover a sum of £609 for improvements and alterations made to the house and shop premises, 22, North Earl-street, Dublin, for the defendants, who are a firm of drapers carrying on business in that city, and was heard by Mr. Justice Holmes and a special jury on Dec. 15 and 16. The defendants lodged £460 in court in full satisfaction of the plaintiff's claim, and counter-claimed for £600 for alleged defective workmanship and materials, and for delay in completion. In the course of the trial, which lasted two days, several witnesses were examined, and the evidence was of a conflicting character. In the result the jury found for the plaintiff for £42 over the amount lodged in court, and against the defendants on the counter-claim.

TRADE UNION RULES NOT BINDING ON EMPLOYERS.—Alfred Gaard, a builder, was summoned to the Highgate Police-court on Monday by a bricklayer named Love for wages said to be due. The complainant said he went to work at seven o'clock in the morning, went to breakfast at eight, and on his return was told by the defendant, "I shall not require you any longer." The complainant demanded an hour's pay beyond the hour he had worked, and produced the Operative Bricklayers' Union Rules in support of his demand. The Bench decided that the defendant was not bound by these Union rules, and dismissed the summons with costs.

AN EXPENSIVE BRICK.—A singular building case was heard before Mr. Lumley-Smith, Q.C., at the Shoreditch County Court, on Monday, the 19th inst., by which Henry Bamber, a cementer, sued Messrs. T. Boyce and Co., builders, of Eagle Works, Hackney-road, to recover £50, under the Employers' Liability Act, for injuries sustained through the negligence of defendants' servant. On the 4th of July the plaintiff was cementing on the basement floor of the Gainsborough Board Schools, Victoria-park, when, whilst stooping, a brick fell

from the scaffolding of the third story, which struck him in the loins and rendered him insensible. The brick fell 30ft. He was carried to the London Hospital, where he remained fourteen days, and could not work for seven weeks. Alfred Page, who carried the bricks, said one brick fell over. Three expert witnesses were called, who said that at such a height a double "guard-board" ought to have been placed on the scaffold to prevent the bricks falling over. The guard-board used was only 9in. high. For the defence, it was contended that two experts said that a 9in. guard-board was sufficient for such a height. His Honour said plaintiff had been guilty of gross exaggeration and misstatement in a letter he wrote to the firm demanding compensation, and he should only give him a verdict of £6.

THE BUILDERS AND THE FLORIST.—LIQUIDATED PENALTIES.—The case of J. W. Wyatt, of Crownhill, and B. Corber, of Egg Buckland, builders, against W. G. Hodge, F.R.H.S., florist and fruiterer, of George-street, for £20, balance due for work done and materials supplied in the erection of two greenhouses, came before the Devonport County Court on the 15th inst. The case was reported in our issue of the 2nd inst., p. 793. It appeared that the houses were to be built in a certain time, which had not been done. For the plaintiffs it was argued that the clause in the contract was a penalty clause, but the defendant submitted that he could claim liquidated damages. His Honour, in delivering judgment, said he had looked up the cases which were cited on both sides, and although it was argued that this was a penalty clause, it was in effect a liquidated agreement. The only point was, supposing he was wrong, whether the defendant had proved damages to the amount claimed, and he thought, assuming that the agreement was by way of a penalty, the damages had been proved. As to the defendant's delay in clearing away the ground for the erection of the greenhouses, thereby hindering the plaintiffs from carrying out their contract in the stipulated time, he found that there was no delay on the part of the defendant. He therefore gave judgment for the defendant with costs.

AN ARCHITECT'S CLAIM FOR FEES.—SWASH V. RAY AND GILMORE.—At Newport, Mon., county-court, on Thursday, the case of Swash v. Ray and Gilmore, which was heard at the last Court, and in which his honour Judge Owen gave judgment for the plaintiff on the claim for £12 odd, and on the counter-claim for the defendants. The case, which was reported in our issues of Nov. 18 and 25 ult., pp. 725 and 753, now came on again. His Honour said that the judgment was for a similar amount against each defendant. It was now agreed that judgment should be for £24 13s. against the joint defendants. An argument ensued as to how the amount of damages should be assessed. It appeared that there was no decision as to the point between architect and owner. Mr. Wallace, for defendants, said that it was likely the case would end in the House of Lords. His Honour advised the parties to come to terms, saying that the costs, if the case were carried to the higher courts, would amount to more than the costs of the original contract. Mr. Wallace said that the plaintiff had wrongfully given a certificate to the contractor, who had erected two houses for the defendants. The plans stipulated 14in. mullions, and the contractor put in only 9in. mullions. Mr. Wallace now contended that the measure of damages was the cost of taking down and rebuilding the bay windows, whilst Mr. Bailhache urged that the damage was the difference between the value of the house as erected with 9in. mullions to what it would have been had the 14in. mullions been put in. It was eventually agreed to refer the question of what was to be done to the houses to Mr. J. Thomas, Bristol city surveyor, the plaintiff agreeing to pay the costs of any alterations necessary. His Honour gave costs to the plaintiff on the claim, and costs to defendants on the counter-claim.

IN RE W. R. PARKER, CARDIFF.—The public examination in bankruptcy of Mr. W. R. Parker, contractor and ex-town councillor, of Cardiff and Penarth, commenced at the Town Hall, Cardiff, last week. The debtor said he had carried on business in Cardiff as a contractor for about eight or nine years, and had lived at Penarth. He had been in partnership with Mr. Pedrette since 1888, and previous to that he had been in partnership with Mr. Geen, of Newport. The heaviest contracts he had taken were the construction of the Ystradgynodwg and Rhondda main sewer. That was now completed, except for a few small matters. He made no money by the contract. A claim for extra work, amounting to £13,190, had been sent in, and had been disputed. The amount of work certified for the Rhondda sewer was £140,000. The firm now owed about £10,345. Mr. Thomas Pedrette, partner in the firm of W. R. Parker and Co., was also examined. He said he had been in partnership with Mr. Parker about four years, but he had not had anything to do with the Cardiff business, his share of the work being to manage the contracts at Reading and Wakefield. The examination was adjourned to the 6th of January.

Our Office Table.

THE London County Council decided on Tuesday not to sell the site for artisans' dwellings in Goldsmiths-row to the East-end Dwellings Company, but to take steps for carrying out their resolution of October to ask the permission of the Home Secretary for the Council to erect dwellings on the site. They also determined not to act with the Middlesex County Council with a view to the acquisition of Alexandra Park, as they considered the purchase-money demanded, £275,000, far too high. An application having been made by the Edinburgh Corporation that Mr. A. Young, the valuer to the council, should be allowed to go to Edinburgh to give evidence as to the tramways arbitration, it was resolved, after much discussion, to give Mr. Young permission to go on condition that he should not receive a fee.

Good progress is being made with the arrangements for a photographic survey of Warwickshire. The proposal is to collect a series of photographs of all the scenes and buildings of interest in the county, so that, should they hereafter be altered or effaced, it will be possible for future generations to see what they resembled in the second half of the 19th century. A strong committee of selection has been appointed, on which are included Mr. Jethro A. Cossins, a well-known Birmingham architect, and Mr. Whitworth Wallis, F.S.A., the curator of the Birmingham Fine Art Gallery, and the collection will be housed by the Birmingham corporation in their galleries. The idea seems to have "caught on" with the inhabitants of Warwickshire, for already the committee have arranged and exhibited at Birmingham some 500 of the interesting photographs received, and at a meeting of the committee held last week, the curator, Mr. James Simkins, announced that he had received and mounted a second series of 421 photographs, while 470 more from negatives actually taken had been promised. It was asserted that the next exhibition would be far superior in quality of work and interest to the one held last year. In connection with the survey record a portrait gallery of "Warwickshire Worthies" will be formed, to be added to at the rate of 50 names of local celebrities a year, and the first instalment of names has been agreed to. The success of the scheme is now so well assured that it is under consideration to make a similar photo-survey of the adjoining counties of Stafford and Worcester.

JAY GOULD is buried in the comparatively small marble mausoleum built for him several years since in a grass-covered knoll on Woodlawn Cemetery, New York City. The tomb was designed by Mr. E. T. FitzMahony, and is a lifeless reproduction of the *Maison Carré* at Nîmes—a hexastyle, peripteral Ionic temple. It is built of Westerby granite, and measures 33ft. by 22ft. and 20ft. in height to apex of roof. The cells are shut in by heavy bronze doors, and measures 20ft. by 70ft., and 13ft. high in the clear. Around the walls are the catacombs on either side. The floor is a single slab of marble, the internal walls are faced with polished pink and cream-coloured Tennessee marble, and the roof is a monolith of granite. At the rear of the cells is the only window, 6ft. by 3ft., which is filled with stained glass representing a choir of angels. The building is roofed with overlapping granite slabs, and the entire cost of the mausoleum was £16,000 sterling.

MR. CHARLES J. FERGUSON, F.S.A., of Carlisle, in a letter to the daily press, reminds us that the buildings of Millbank Prison, now in course of demolition, were the first of importance in England in which the modern use of concrete in foundations was adopted. He adds: The success which attended the use of this material at Millbank—though it was not until the foundations of two pentagons carried on piles had failed, that Sir Robert Smirke was called in and concrete was adopted—led to the more extensive use of concrete, and to the almost entire disuse of piling and planking, and gradually developed still further uses for concrete—a process that is still going on.

HERR ALWIN NIESKE, of Altharzberg, suggests a method for the preparation of an absolutely waterproof cement, consisting in the addition to ordinary cement of acetate or palmitate of

alumina. By further adding chromate of magnesia to this mixture, the cement is made refractory as well as moisture-repelling. The proportion of palmitate of alumina to be employed will vary according to circumstances, the nature of the mortar or cement, and the character of the work to be done; but 10 per cent. of the palmitate would be a good proportion for any kind of hydraulic mortar. If the cement is needed to resist humidity, and be at the same time refractory to fire, a mixture is made in about equal parts of the cement mortar with the palmitate and a chromic magnesia prepared with oxide of chromium, 32 to 42 parts; alumina, 18 to 22 parts; magnesia, 18 to 20 parts. The mixture of these earths, wetted with water, is formed into briquettes.

THE Lord Mayor has received at the Mansion House a deputation, who presented addresses from the corporations and plumbers of Glasgow and the West of Scotland, and those of Edinburgh and the East of Scotland. The documents, which were beautifully illuminated, contained congratulations to Mr. Alderman Stuart Knill on his accession to office, and conveyed the thanks of the signatories for his warm support of the movement for the national registration of plumbers. Hope was expressed that the Plumbers' Registration Bill might be entered on the Statute Book during his term of office.

In describing the exhibits at the Sanitary Museum at Highgate last week, we inadvertently omitted to mention the very instructive collection of sanitary appliances and fittings presented by Messrs. Hayward Tyler and Co., of Whitecross-street, E.C. The "full-flush valveless" closet, with ornamental basin, and the "elastic-valve" closets with flushing cistern and with flushing basin, are exceptionally good, and deserve the attention of architects and builders. One is fitted with "underseat" regulating valve and extra large outlet. The "Tylerox" pedestal wash-down closet, with waste-preventing cistern, and the examples of earthenware urinals and flushing cisterns, also the plumbers' fittings, are improvements which are well worth the inspection of every architect and builder who are anxious to specify or introduce the best workmanship.

For the preservation of ironwork from corrosion, tar-smoke painting is recommended by the French Marine Department, who have issued instructions. Tubular boilers, when not in use, are to be filled with water, to which a distinctly alkaline reaction has been imparted by a small quantity of lime or soda. The parts inaccessible by the brush are to be preserved by burning coal-tar under them, the smoke of which, condensing in the cold tubes, forms a protecting coating which prevents corrosion. The external parts can be painted with red-lead or coal-tar.

CHIPS.

The Legislative Council of South Australia passed, on Thursday in last week, the Bill authorising a loan of £1,016,000, to be employed mainly for railway construction and waterworks.

On Saturday several members of the Royal Family visited Paddington to take part in the ceremony of laying the foundation stone of the Clarence Memorial Wing of St. Mary's Hospital, the cost of which is estimated at £100,000. The new wing will bring up the accommodation of the hospital to 380 beds, and will contain a medical school and college.

The Chichester town council have adopted a scheme for the extension of the borough boundary to include the urban population that has sprung up without the area of the city. The scheme, if carried out, will add 3,204 to the population, and £3,386 to the rateable value.

In our notices last week, *re* the opening of the University College, Liverpool, and the cathedral extension, Manchester, we omitted to mention that Mr. Geo. Wragge made and fixed the whole of the wrought iron casements for the former to Messrs. A. Waterhouse and Son's instructions, also the gun-metal casements used for the latter work.

The infectious diseases hospital, Herne Bay, is being warmed and ventilated by means of Shorland's patent Manchester stoves and patent Manchester grates. For the extraction of the vitiated air, an outer metal casing is fixed round the outside of vertical smoke-pipe leaving space all round (*viz.* between the smoke-pipe and the outer casing); this forms a simple and excellent exhaust shaft for the vitiated air, and terminates just above the ridge of roof with one of Shorland's exhaust cowls. These warming and ventilating appliances are supplied by Mr. E. H. Shorland, of Manchester.

FRIDAY, DECEMBER 30, 1892.

DETAILS AND TENDERS.

GREAT artists have always paid attention to details. The sculptor is not fully satisfied with the general outlines and proportions of his figure group; his ambition is to perfect the design in those minor qualities of modelling the draperies, facial expression, and attitudes of his figures, which he sculpts in marble. The painter, after he has satisfied himself with a general sketch of his subject, and has decided upon the general composition and grouping, light, and shadow, devotes himself to various details, such as the study of anatomy, costume, drapery, or trees, waves, or other accessories which are to make up the particular subject he has selected, for it is attention to these details which prove the painter's knowledge and resources. In a greater degree the architect is called upon to make himself proficient in those various branches of construction and ornament which minister to the convenience and pleasure of his building. In a greater degree, we say, because an art whose sole aim is to give pleasure to our sense of vision, like painting, stands in a different position to one like architecture, in which the functions of art have to be associated with those of utility. A number of separate details go to make a building habitable, comfortable, and pleasant to the senses. Imagine for a moment what a room would be without a good floor, firm and comfortable to the tread, well-fitting doors, and windows that can be opened or closed without trouble, a fire-grate that will throw out the proper amount of heat, a well-designed chimney-piece, a mode of ventilation that will insure a proper supply of fresh air to a comfortable degree of warmth. We might even go further, and mention the value of secure and easily-adjusted fastenings and furniture to our doors and windows. All these details go to make a design complete and satisfactory to people of good taste; though it is remarkable to find some individuals—building owners and promoters—satisfied with badly-designed houses, and even churches, while they try to bestow every care upon the internal fittings and furniture. We often see a hideously-planned room, with bad mouldings and poorly-designed wood doors, furnished with the most correct "art" chairs, tables, and cabinets, as if such "high-class" furniture can look in keeping with, or harmonise well with, the wretched proportions and details of the room in which it is placed. The dictum to be enforced upon the ordinary British house-builder, or building committee of a public edifice of any kind, is that there must be *fitness* in our art, that buildings should be designed *fitted* for their receptive functions, and that their furniture and details must harmonise with the architect's work. A most obvious principle in our appreciation of art, whether it be music, the drama, painting, or sculpture, is that physical conditions or aptitudes for the enjoyment of them exist. Our appreciation of a stirring dramatic play or of a good concert is enhanced materially when we have comfortable seats, when cold draughts or oppressive heat are avoided, and when we can see and hear without straining our necks.

The same principle holds good in the contemplation of architecture and the subsidiary details which contribute towards it. We can enjoy a well-designed piece of furniture, a handsome vase, or a piece of sculpture or

painting all the more if it is surrounded by a congenial atmosphere or a background in harmony with it. It is lost or spoilt by being placed in an ugly recess, or against walls whose colour is out of key. The same principle of suitability or fitness ought to govern the architect in the design and selection of details, by which we mean not only architectural features, like gables and turrets, and towers and ornament, sculptural and otherwise, doors and windows, but the selection of materials and fittings. These are left to chance. Many of our finest buildings are spoiled by imperfect or inferior detail. Directly we go up to them, their charm of outline and good composition is gone. Doorways and windows are meanly carried out, the moulded work is meagre and commonplace, the woodwork is poor and thin, the fittings are inferior. A poverty-stricken look pervades the exterior in the columns, mullions, and projecting members, while the interior disappoints by the flimsy fittings, which are generally wanting in massiveness and character.

One characteristic that distinguishes the work of the real architect is the solidity of the stone and woodwork. We see the stone pilasters or mullions of substantial width and thickness, the reveals and jambs are deep, the wood frames of sashes or casements large and solid. Another characteristic is that ornament is reserved for points of interest. The doorway is not insignificant, but important, upon which the designer has bestowed extra pains. If there is little money for decorative treatment, this one feature at least receives its due share—all else is plain and solid; but upon the porch or the doorway is lavished the art of the mason, the modeller, or the stone-carver. If there is one important room, such as a public hall, it is also made a feature. The windows receive an extra share of attention, the piers have pilasters; gables and chimney-shafts are made features of interest.

The tower or turrets are other points upon which careful attention is bestowed in the shape of good profile and terminations, and in the details of windows and dressings. It is far better that, if the sum to be expended on ornament is small, it should be bestowed on these features, and the rest left quite plain, than that the whole exterior should be covered with poor ornament, weak and thin. The latter is, however, the course followed by many architects; they strain everything to make the principal façade ornamental, the interior is sacrificed to obtain a little flimsy tracery to the windows, or a little cheap carving or ornamental brickwork—in short, the idea of the designer of this class is to make a show of art at little cost. It is this sort of art-commercialism, if we may so call it, that is just now rampant. Everything must be smothered with so-called ornament. Where to put detail is one of those questions which seldom appear to be thought of. We find a great deal of it wasted, thrown away in positions that cannot be seen, or squandered on parts of the building which ought to be perfectly plain. Rules are sometimes misleading in these matters. No doubt it is a good general rule not to put too much detail near the ground, but to increase its quantity on the edifice as it ascends, and some of the best buildings conform to this principle. Their plinths and wall-spaces are severely plain for some height above the ground. Pugin knew how to apportion ornament for some of his finest buildings, like St. Augustine's, Ramsgate, and the Cathedral, Southwark, amongst others. The value of this rule—the severe plainness of the lower portions of the buildings or gradation—we find observed in the works of the late Mr. Street, and in those of Mr. Pearson and Mr. Sedding. But it is a principle commonly forgotten in works of less eminent masters. The rule we have noted of increasing the degree of detail and ornament as we ascend

is, however, not invariable; there are some places where the eye rests more than others, and where the detail ought to be more frequent, finer, and more delicate, as the tympana of doorways and gables, and other parts which are near the eye. In fact, we cannot observe any rigid rule in these matters. The artist's touch here and there gives life and interest to the canvas or the stone. But there is another thing yet besides gradation of detail; there is a scale of minuteness and finish. We often see elaboration thrown away about a very commonplace thing;—an over-enriched cornice forty or fifty feet high; while close to the eye we have a similar cornice, stringcourse, or panel, coarse, and large membered. These are matters of taste and feeling which no amount of knowledge and formulae will teach. We have been discussing external detail: the details of the interior are equally to be studied, and these include all those fittings and finishes which increase the convenience and comfort of a building. Our floors are often constructed without regard to their strength and impermeability. They transmit sound and gases. Though a number of patented systems are on the market for construction and flooring, architects are apt to overlook them because of their expense, and to use instead very inferior materials and labour. Then we use old methods of walls, partitions, and roofs equally faulty in their permitting sound, heat, and cold, to pass through them. Hollow-wall construction, fireproof lathing and plastering, slag-wool, are methods and materials which the architect has not turned to the best account. Even in the important means of the conservation of heat, by employing non-conducting materials for partitions and floors and roofs, we have made very little headway. Where to place our fires, heating chambers, and radiators so as to prevent loss of heat; how inlets for cold air and outlets for the vitiated atmosphere of our rooms and churches can be made to serve in this direction, and at the same time aid the propagation of sound in the latter, are points which have scarcely been thought out with any skillfulness. Empiricism is still the order of the day in these subjects, because architects have too long left them to engineering experts and have been in the habit of treating them as details unworthy of the artist's regard. This sentiment has been pernicious to architecture, for it has encouraged the spirit of separatism in art. In other things, like electric-light fittings, door furniture, fire-grates, the architect has little or nothing to do with them; they may be intensely ugly fittings, out of "key" with everything else, but they are selected under the contract. Our public buildings equally suffer in the details of fittings and decoration: a well designed set of rooms, hall, and staircase are atrociously decorated and fitted. The details have been handed over to wholesale decorators, gas-fitters, stained-glass makers, and others, and if the architect is not particular as to colour and design, the prospects are his whole work is sacrificed to a sort of cheap commercial art painful to contemplate.

The profession cannot expect to find an improved condition of things, till they take these details under their particular care, and endeavour to look upon them as an inseparable part of the design. For reasons not difficult to understand, especially when a low tender is indispensable, there is an aptness to look upon the building as architecturally complete, after the painters have left it, all the other trades being regarded as subsidiary or superfluous. These trades include the ironmongery, lock furniture, hot-water apparatus, electric bells and fittings, gas-fitting, decoration, stained glass, metal-work and furnishing—every one of which ought to be under the control of the architect in a special manner. They are, in fact, the finishing touches of the archi-

tectural design. Tradesmen of special goods, manufacturers, and artists have their directions too frequently from the contractor or the owner; the prices have been cut down to bring the total to the required amount. Their interests, as well as that of the architect, would be better served by a course which places all the trades under the immediate direction of the architect rather than that of "divided authority." Even "provisional sums" when introduced into specifications, do not guarantee that attention which they are intended to afford. Let each fitting and material receive the "hall mark" of the architect's approval if they are not really designed by him.

BUILDING BY-LAWS.

THE operation of the Local Government Board By-laws has been pretty general and uniform in large towns, as might have been anticipated. Yet we find here and there some difficulty in enforcing the model regulations upon builders who have been for many years their own masters, and who were allowed to do things of the most questionable kind in some towns. The inevitable friction of a newly introduced code has been considerable, so much so that local authorities have found it extremely hard to enforce their new by-laws. Penalties are constantly incurred by refractory builders and owners, as our Legal Intelligence weekly informs us, and in large towns the offices of surveyor and inspector are by no means light ones, especially when these officials have to cope with a number of "jerry" builders and house-owners who are also members of the corporation. Considerable variations and differences of opinion prevailed before the Local Government Board issued their model by-laws in 1877, prior to which, varying modes of construction were the result of leaving every urban authority the option of making by-laws of their own. These differences have left prejudices which still linger, and prevent any uniformity of practice;—e.g., to bring a building under the operation of the Act, it is necessary to prove it to be a "new" building. As our readers are aware, it is difficult to prove the newness of a building, as it may be an alteration or conversion of an old one, or a fire may have destroyed a considerable portion of the premises, rendering it not very easy to ascertain the extent of the damage or the reconstruction. The 159th section provides a limit by enacting that "the re-erecting of any building pulled down to or below the ground floor" shall be considered the erection of a new building, but the term "ground floor" may mean the floor level or the story, including the walls and ceiling of the ground floor. Builders are constantly found to interpret the clause in the latter manner. In another instance an old building is converted piecemeal, first by the alteration of internal walls and partitions, then by the removal of staircases and floors, the builder thus evading the law. We have frequently had to record cases of reconstruction in this gradual manner, by which a builder is practically enabled to erect a most objectionable and unsafe structure without any of the precautions required by the by-laws. It becomes necessary to check these insidious attempts to build by a continual observation being kept, or by periodical surveys being made. We can imagine a building under process of repair or conversion occupying a considerable time, in which case the builder might take advantage of the six months' notice, and contend that as the work was begun before any complaint was made, or before that period had commenced, no liability had been incurred. But the Act does not, we believe, give the surveyor the right to make inspections of premises at the commencement, so as to prevent the error or evasion.

Correspondents often desire information respecting the interpretation of certain by-laws. The term "topmost" story has given rise to much debate in reference to the question of the schedule of thickness of walls of dwelling-houses, and builders are very apt to take advantage of the rule in the case of two-story dwellings, one of which stories may be the space in the roof. The clause relating to concrete, a 6in. layer of which is provided over the site of every domestic building, is constantly a subject of question, and builders frequently evade the by-law altogether. Hollow walls and damp-courses are matters of constant misunderstanding, and it is for this reason requisite to print and distribute the sections of walls with cavities in those cases where the damp-courses have to be provided both above and below the ground level. To illustrate the schedules of wall thicknesses, many boroughs of importance publish sections, also the modes of dealing with recesses in walls, beams on party-walls, chimneys and hearth construction, as well as the modes of draining with sections of disconnecting siphon traps, mode of laying and ventilating drains, ventilating details to closets, and the modes of connecting sinks and baths. As an example we may refer to the excellent by-laws for new streets and buildings issued by the borough of Sheffield, those of the Bournemouth Corporation, and many others. These publications make it easier to understand the meaning of certain clauses, and have an instructional value besides. In this connection we hope before very long many of our leading urban authorities will follow the example of the Hornsey Local Board, who have fitted up a very complete sanitary museum at Highgate, in which almost every important sanitary appliance and material can be seen. A complete model to a full-size scale represents the approved system of drainage and ventilation for a dwelling-house, in which the pipes and drain through the house are shown in section, the latter embedded in concrete, with manhole and open channel pipes, the connection of the soil-pipes with closets and baths on each floor, and the ventilating pipes and anti-siphonage vents. Such a model would convey all the information found in the by-laws relating to the drainage of buildings and water-closets. The sectional model also shows the cavity structure of outer walls bonded by stoneware ties, the damp-courses and construction of floors, &c.

The museum may be made to represent every one of those points in the construction of buildings and drainage which are provided for in the by-laws, so that builders and owners may go and see what they are expected to provide under the Act. There are several by-laws which are not clearly understood by architects; one of these is in respect of half-timber work. The rule that framing is to be executed with a thickness of brickwork, 4½in. at least, behind every timber is certainly open to the objection that this class of timber framing encourages a very flimsy kind of construction, as the timber must be of small scantling, and only show on the face. Many other by-laws may be cited which are not very clear or give room for doubt, there are other local differences to consider, in all of which cases there ought to be some recognised authority to appeal to when disputes arise. We know that these differences of interpretation occur, the by-laws being variously interpreted.

IRON ARCHES OF LARGE SPAN.—V.

CAST IRON.

FROM the very great discrepancy that exists between the relative depths of an arched iron rib, when compared with that of a straight beam or girder, one might be at first led to expect that a very considerable saving of material would result from the employment of the former

type of construction. Theoretically, this is the case, but practically all the advantages prescribed by pure theory are very much reduced, in order to meet the conditions of actual loading and the exigencies of heavy and continual traffic. If D be the depth of an ordinary plate girder of wrought iron, and L its span, then the value of D would lie between $\frac{L}{14}$ and $\frac{L}{16}$. For a lat-

tice or open web girder the range would be from $\frac{D}{12}$ to $\frac{D}{8}$, although the latter proportion is not

usual in England. It is, however, a very common one in American truss bridges, and is, when properly designed, a decidedly economical ratio of depth to span, especially in girders of large dimensions. From the examples we have already adduced in our preceding articles, as well as from others to be subsequently alluded to, the proportion of the depth of the actual cast-iron ribs to their clear span will be found to be from one-fortieth to one-sixtieth.

The depth of the rib has nothing in common with the depth of a horizontal girder, for if it had, and if it entered into the calculation of the stresses, we should have, not a reduction, but a notable increase in the amount of material required. The economy of the rib form proceeds from another source, which will become apparent as we advance further with our subject. It will, at the same time, be understood, from what has been previously placed before our readers, that the depth of the rib itself will affect all calculations in which the "moment of inertia" is

involved, and, in treating of the deflection of ribs, the value of x in the equation given in our first article, $1 = \int b x^2 dx$, will be very different from that used in the case of a horizontal girder. In Fig. 10 let $A B$ represent the curve of pressure in an arched rib, make $BC = V$ and $AC = \frac{L}{2}$, and put $W =$ unit of loading per running foot of span or arch. Let $S =$ the stress at the centre of arch, and $HT =$ the horizontal thrust; then $S = HT = \frac{WL^2}{8V}$. If D be the depth of a horizontal girder under similar conditions of span and loading as the arched rib, then the stress at centre $= S = \frac{WL^2}{8D}$. But $V = D$, and, therefore, the two equations become identical, and the versed sine or rise of any arch is taken as equal to the depth of an analogous straight beam.

The actual depth given to an arched rib depends, to some extent, upon the length of the span, the rise of the arch, and the absolute available headway from the springing to road, or formation, level, as the circumstances may require. The depth of the rib in cast and also in wrought-iron arched bridges is often maintained constant, although the stresses vary in an increasing ratio, from the crown towards the springing. This increase again depends upon the nature of the curve adopted for the rib and the character of the loading. If the load be uniformly distributed, as it is usually assumed to be in structures of the class we are considering, the stresses will also be uniform throughout the rib, provided the curve of the arched rib be of the parabolic order. In ordinary cast and wrought-iron arches the circular curve is generally adopted; in the first place, for the sake of practical convenience, and, secondly, because in all instances in which the proportion between the span and rise do not exceed certain limits, the

curves differ very little from each other in actual contour, and the stresses, consequently, vary in similar small ratio. Westminster Bridge must be taken as an exception to this rule, as the real curve of the arch is one parallel to a parabola. Its construction is also somewhat peculiar. A cast-iron arched rib bridge, designed by the same engineer in York, is in the form of a Tudor arch, and presents a very striking and unusual appearance, although some aesthetic critics have taken exception to the pointed character imparted to the arch at the crown.

It may be readily shown that the common formula for the value of S in both girder and arch is, in each case, only a particular form of the more general formula for the stress at any point of each example. To take the straight girder first. Let the girder be supported on the abutments A and B , and let it be uniformly loaded with a total weight, W . The stress at the point P is required, the said point dividing the girder into two segments, x and y . Putting D for the depth of the girder, and S for the strain at P , we have $S = \frac{W \times x \times y}{2DL}$, in which L = the span of the girder. Making $x = (L - y)$, the equation becomes $S = \frac{W(L - y)y}{2DL}$. At the abutments $y = 0$ and S has the same value. At the centre of the girder $y = \frac{L}{2}$, and, substituting this value for y in the above equation, we obtain $S = \frac{W(2L - L)L}{8DL} = \frac{WL}{8D}$ = the stress at the centre already given.

In Fig. 12 let MM represent a portion of an arched rib, the vertex, or crown, being at N . Put w for the unit of load, and let the stress be required at the point D , situated at a distance, x , from the crown N . Through the point D draw a tangent to the curve MN . Make $DE = w \times x$ —that is, equal to the load between the point D and N . From E draw the horizontal line EC , meeting the tangent at C , and making with it the angle DOE , which put equal to θ . The horizontal line EC is equal to the stress at the centre, which put = H . The thrust on the arch at the point D is represented by the line CD , which make equal to T . Then $T^2 = H^2 + (w \times x)^2$. At the centre $x = 0$, which, it may be observed, is the same value which, in a straight girder, it has at the abutments, and the latter term of the equation vanishes, and $T = H = \frac{WL}{8D}$ as before.

There is another useful expression for T , which may be stated $T = H \times \secant \theta$. At the crown of the arch, the tangent CD becomes horizontal, and $\secant \theta = 1$; so we have, as before, $T = H$. If we square both sides of the equation, $T = H \times \secant \theta$, we obtain—

$$T^2 = H^2 \secant^2 \theta$$

and equating this expression with the other value of T^2 obtained above, we should have $H^2 \times \secant^2 \theta = H^2 + (w \times x)^2$. It is not difficult to prove this to be the case. Put $(w \times x) = W$. In Fig. 12 the line $DE = W$, and by the diagram we have—

$CD^2 = DE^2 + EC^2$, or $H^2 \times \secant^2 \theta = H^2 + W^2$. From the Fig. we obtain $W = H \times \text{tangent } \theta$, and, therefore—

$$H^2 \times \secant^2 \theta = H^2 + H^2 \times \text{tang.}^2 \theta.$$

But $\text{tang.}^2 \theta = (\secant^2 \theta - 1)$, and we thus obtain—

$$H^2 \times \secant^2 \theta = H^2 + H^2 (\secant^2 \theta - 1) = H^2 \times \secant^2 \theta,$$

thus establishing the identity of the two equations. It may be remarked here that, *mutatis mutandis*, the formulæ giving the stresses on an arch apply equally to the stresses on the chain of a suspension bridge: compression in the one case becomes tension in the other.

Before proceeding to give one or two examples of the method of designing and constructing cast-iron arched ribs of the most recent type, and deducing therefrom a practical comparison between them and other forms of girders, it will be advisable to inquire into the reason why the incontestable economy of the cast-iron rib is not fully realised in actual practice. It must be borne in mind, in dealing with the stresses upon iron bridges, roofs, or other engineering and architectural structures, that the actual stress upon any one particular section is not of so much importance as the uniformity of stress upon every

section taken in the aggregate. By the term uniformity of stress, is not meant that the stress is uniform throughout the whole girder or rib, but that each unit of area is subjected to the same unit of stress. The insurance of this condition was the great difficulty experienced in the early designs of iron structures. If not carried out in practice, the result is that when the beam or girder is subjected to the test of a breaking weight, it yields very frequently long before the ultimate compressive or tensile strength—which ever it may happen to be—of the material is reached. The quantity of material necessary at any part of an iron girder, rib, or other form, must be proportioned according to the nature of the stress, whether tensile or compressive, longitudinally, or of a vertical shearing character. In braced, trussed, lattice, trellis, and open web girders generally, the position of the part under strain has to be carefully considered, with reference to the particular unit strain to be adopted, especially in bridges of large dimensions, in which the ties and struts are of correspondingly similar proportions.

If S be the stress upon any part of an iron rib or beam, and C the unit adopted—that is, the stress per unit of area—then, if the area be represented by A , we have for the necessary amount of metal at that part, $A = \frac{S}{C}$. It is evident,

therefore, that if the value of C could be made a maximum for each particular description of stress throughout the whole structure, the economy of material would also be a maximum. This, however, can never arise in actual practice, as is apparent from what has been stated in our previous articles on this subject regarding the moment of resistance of the individual fibres of a rib or girder. The value of I for any particular fibre is proportional to the square of its distance from the neutral axis that is proportional to x^2 , and D being the depth of the rib, x has two limits, $x = 0$ and $x = \frac{D}{2}$. The horizontal

girder has the advantage that the lines of pressure, both compressive and tensile, are susceptible of comparatively small deviation. But in the rib, the line of centre of pressure may, under different conditions of loading, alter very considerably, and thus materially modify, if not almost destroy, the theoretical assumption of uniformity of pressure. It is no doubt partly due to this reason that all existing examples of cast iron arched ribs are subjected to, comparatively, a small unit strain, as will be pointed out more fully in a future article.

STABILITY OF WALLS ON SOILS.—X.

(Concluded.)

Graphic Representation of Equal and Unequal Pressures.

IN order that the stability of a tall structure, whose stability depends on gravitation, when acted on by force in a lateral direction, be not endangered, the position of the centre of the resultant of the lateral and vertical pressures intersecting the base should not deviate from the centre of resistance or centre of gravity of the horizontal section more than one-sixth of the effective diameter in the direction of deviation.

By the law of the variation of unequal pressures due to the tendency to overturn a plane, the decrease of pressure at one end corresponds with the increase at the other end.

When the centre of pressure is eccentric of the figure pressed, the pressures at the ends vary uniformly from end to end in the line of eccentricity, according to its degree. The graphic representation (Fig. 27) of the entire uniform perpendicular pressure applied at the centre of gravity of a surface is a rectangle, as $A B, a b$, and that of an unequal pressure applied eccentrically is a trapezoid so long as the resultant pressure is applied within the middle geometrical third of the pressed surface. But if it be applied at the limit of the middle-third—i.e., at one-sixth of the diameter of the base from its geometrical centre as at N , the figure representing the distribution of pressures becomes triangular as $A e B$, thereby indicating that the normal forces vary uniformly from zero at the end A to a maximum at B , the base of the triangle.

Moment of Overturning.—When the resultant force is applied within the extreme one third of the base, as at J , which is the one-third point of

the length of the semi-base, there is (1) a negative or upward pressure at the end A , causing tension or uplifting there of the upper surface of joint; (2) a zero or neutral point of pressures in the middle of the base C ; and (3) a maximum positive pressure downwards at the end B . These mechanical phenomena are indicated by the triangle $c d B$, the tension or uplifting being indicated by the extension of the side $c d$ of the triangle lying above the base $A B$. When there is no counter resistance at the end A , such as anchor or hold-down bolts, or the cohesion of cement mortar in the bed joints of masonry, then the practical bearing surface which supports the weight of the structure is thus reduced to one-half of the area of the base, whereby the former mean unit pressure on the supporting base is doubled, and the structure becomes unstable.

Moment of Overturning Implies Rigidity.—The treatment of the problem of safety thus as dependent merely against overturning on an edge as is sometimes done—i.e., a question of stability alone—involves the dangerous idea of regarding the structure as a perfectly rigid mass throughout, which the tiro must beware of.

Overturning Tendency of Wind Pressure.—The horizontal pressure of strong winds against the high walls and other exposed parts of buildings, towers, tall chimneys, especially in exposed positions, will tend to shift the points of concentration of weights of the superimposed structure more or less upon the leeward side of the static centre of the foundation base. The overturning force only causes a deviation of the point of concentration of weight towards the leeward side, but does not increase or diminish the total vertical weight.

Suppose in Fig. 28 the portion $c d' A B$ above the base $A B$ to represent a part of the vertical outline section of the extremes and centre portions of a tall mill chimney. Assume H to be the geometrical centre of the exposed windward side, and also to represent the point of its horizontal intersection with the vertical axis passing down through the centre of gravity of the mass, and therefore to be vertically above it.

Stability against Crushing.—In very tall structures acted on by wind force, such as a very lofty chimney, the moment of the wind-force leverage pressing the weight of the masonry, &c., of the entire mass with a reinforced intensity upon the footing courses or lower bed-joints of the masonry on the leeward side, and then be reacted on by a soil having, perhaps, a safe fourfold bearing power, would inevitably rupture and crush the projections of the footing courses before any overturning of the superstructure could more than begin.

Yielding of Overloaded Foundations.—A chimney such as is shown in portions in Fig. 30 could not be tilted by a lateral force so as to stand upon the toe of its footings below a , and thereby support all the weight of the entire superstructure, as if the footings remained perfectly rigid, as shown at A . The portion of the footings which acts as a cantilever must in such a case be ruptured or sheared off, and more or less deformed and crushed, as sketched at B , Fig. 30, before overturning to any extent could begin. The shank at the leeward side b , heretofore thus of its footing support, would more readily sink and crush into the soil. But, by the time the inclination in Fig. 30 is reached, there would be a tendency to sliding and splitting-off of the bottom masonry courses, whereby the superstructure would then collapse and be strewn upon the ground. A factory chimney at Ringsend, Dublin, 65ft. high, base 14ft. by 15ft., was demolished by a charge of 5lb. of gun-cotton (equivalent to $\frac{1}{3}$ rd of the requisite quantity of gunpowder) distributed in the same side of two corner piers. The chimney by the force of the explosion shook, and then leaned over about 30° , when it fell, the top striking the ground about 30ft. from the base. The debris was scattered about to the extent of 50ft. from the base. The brickwork bed-joints would thus slide upon the lower courses, pushing off before them more or less of the outside shell below on the leeward side, as indicated at $a b$. From the fact that the position of the top striking the ground was 30ft. from the base, the estimated angle of inclination before its collapse must in reality have been less than 30° , because $65\text{ft.} \times \cosine \text{ of } 30^\circ \text{ from vertical} = 55.5\text{ft.}$ [“Occasional Papers,” Royal Engineers’ Institute, Vol. II. (1873), p. 174.] When a soft soil is overloaded, the overturning of a structure submerged more or less in it in-

volves to some extent the properties of hydrostatic displacement.

Comparative Strength of Offsets and of Footings.—At pp. 419 and 518, *ante*, brief reference was made to the proper designing of footing offsets of any materials—i.e., of designing each offset separately, according to its individual cantilever action at the face of the wall-base; but inasmuch as many footings are erroneously arranged merely by rule of thumb according to the requirements of the Metropolitan Building By-laws, 1855, and the Model By-laws of the Local Government Board, in which their projection and height shall be at least half the thickness of the wall-base, which are insufficient both as regards the transverse strength of the brickwork footings, and also that of the underlying 9in. thick of concrete bed thereby required when the footings are not underlaid by a solid gravel bed. Such footings must necessarily yield before even less than 1 ton per square foot be loaded on them in a soft soil.

Stronger Footings in Soft Soils.—Their insufficiency is readily illustrated by the results of experiments at Akra, near Calcutta, with first-class Akra brick and Sylhet lime mortar, with two parts of soorkee (finely-crushed broken brick) laid in splayed footings, whose projection and height were each the whole width of the wall-base, the bottom course of bricks being laid double, adding $\frac{1}{4}$ th more to the height. The piers were three months and two days old, and the footings cracked right up to the base of the wall with a load of $1\frac{1}{2}$ ton per square foot of footing area. The relative strengths of the footings in the two cases would make the Metropolitan footings to crack in like manner with a load of $\frac{3}{4}$ ton per square foot of footing area, assuming the brickwork in the two cases to be of equal quality, and that the soils were of equal consistency. The undisturbed alluvial soil of Calcutta (which, it may be observed, corresponds to that of Lower Bengal) has the following bearing power:—When the trial pier was laid at 4ft. depth, it sank as under—with 1 ton 3-16in., 2 tons 1in., 3 tons 3 1-16in. per square foot; at 8ft. depth, with 1 ton 3-16in., 2 tons 11-16in., 3 tons 1 13-16in. per square foot; at 11ft. depth, the sinking was much greater than the above. But inasmuch as “splayed footings” are usually built with $\frac{1}{4}$ -brick offsets, the angle of the splay would be about 53° instead of 45° , and consequently the $\frac{3}{4}$ ton would be increased to 0.96 ton with a double bottom course of brick. The relation of the strengths of the two models of footings, the “Akra” having double the depth and projection, in terms of the wall-base, that the “Metropolitan” model has, may be thus formulated:—If $\frac{d^2}{l} \times 1.5$ ton represent

the strength of the “Akra” model, then $\frac{1}{2} \frac{d^2}{l} \times 1.5 = .75$ ton = relative strength of the “Metropolitan” model.

The above experiments were made by H. Leonard, M.I.C.E., late chief engineer P.W.D., Bengal. *Indian Engineering*, Dec. 1st, 1888.

Brickwork Footings.—At p. 419, *ante*, it was pointed out that the reactions at the centre of the sum of the offsets of the footings outside of the face of the wall-base should be estimated. The data (R and offsets) for “best hard” and “hard” brick footings given in the table at p. 420, *ante*, were estimated on the basis of the transverse strength of single bricks, which would be suitable for footings on a very hard and sensibly incompressible soil; but when soft, alluvial soils are to be dealt with, such as that of Calcutta, the ratio of the projection l of footings beyond their wall-base to depth d , should be, for the “Metropolitan” model footings, at most only one-half, because the 1.5 ton and .75 ton loads represented respectively the “breaking” strengths of the two models.

Referring to p. 420, *ante*, a formula was given for readily computing the projection p of footing offsets in terms of thickness of the course t , both in inches, i.e.:—

$$p = \frac{1}{2} t \sqrt{\frac{\text{Modulus of Rupture R}}{\text{Pressure, tons per sq. ft. P}}}$$

R being in pounds per square inch. The table in same page gave the projection for one ton pressure on footings per square foot, and for simplicity a note was appended that for other pressures it was suggested to use a multiplier or fraction. It would, however, be a nearer approximation to use the following fractional parts of it—viz., for $\frac{1}{2}$ ton, $\frac{2}{3}$ rd; for 2 tons, $\frac{3}{4}$ rd;

for 3 tons, $\frac{1}{2}$ to $\frac{3}{4}$ ths. Thus the projections for the following materials in table, computed by the formula, in terms of thickness, are—

	$\frac{1}{2}$ ton.	1 ton.	2 tons.	3 tons.
“Best hard brick”	2.7	1.9	1.36	1.1 times t .
“Hard brick”	2.0	1.4	1.0	0.8
Portland cement concrete	0.8	0.6	0.43	0.35

Concrete Footings.—There are often cases in which useful local materials, suitable for “aggregates” of concrete, are readily available for footings, and consequently when concrete would be more economical than brickwork. Brickwork should always be of hard burned or “blue” brick, laid in hydraulic lime or Portland cement mortar. True economy in deciding whether brick or concrete is desirable in footings in particular cases can only depend upon the relation of their expense to the transverse strength obtainable in either case, for both are alike weak and uncertain, or otherwise, according to the character of the materials and workmanship put in them. The concrete “splay” is a continuous bevel or slope down from the base of the wall to the top of the square toe of the concrete bed proper, like an inverted bracket or corbel on each side of the wall-base. There is, however, one important principle involved in reaching the decision, which must not be lost sight of—namely, the concrete in the footings and underlying bed when in a homogeneous monolithic mass can be estimated as of one solid depth with the “splays,” whereas the brickwork footings with the underlying concrete bed must be estimated separately. As the transverse strength is as the square of the continuous depth, it is evident that the square of a number is always greater than the sum of the squares of its parts. Allowance must be made for the shrinkage of concrete of $\frac{1}{10}$ th to $\frac{1}{12}$ th of its height, according to the “closeness” or “openness” of the aggregate employed.

Unequal Distribution of Vertical Pressure.—When the wind-force is acting in the direction

of the horizontal arrow at H, Fig. 28, it has the tendency to depress the end B, and to raise the end A of the base of the chimney, the degree of displacement depending upon the precise point on one side of the geometrical centre of the base in which the resultant force of the wind and the load intersect the base. Thus, if it be distant from the centre C of the base $1/6$ th of its length, the maximum pressure at B is twice the ordinate Aa, Fig. 27, and the pressure at A is zero, A representing the length de , Fig. 29, of a rectangular unit, $defh$, on plan of the horizontal base of the chimney whose central transverse axis is A B, Fig. 29. The adhesive and cohesive strength of the mortar of the bed-joint of the wall-base of the chimney, represented in vertical section by A B, Fig. 28, may increase the stability; but in practice this strength is disregarded in the data of the estimate of the stability of the structure, as it may be impaired by inferior quality, or be dislocated by unequal subsidence. The ordinate N g, Fig. 27, passing through the centre of gravity of the triangle A e B, equals the mean unit value of the resultant pressure along the line N, 1-6 on plan, Fig. 29.

If H, Fig. 28, equals the total pressure of the wind-force concentrated at the centre of pressure e' , and its length be laid off by scale from the vertical axis e' along to i , then if W equals the total weight of the chimney above A B, and be laid off by the same scale downwards from e' to h , and the parallelogram be completed, the diagonal from e' will intersect the base in the point of application N of the resultant pressure derived from these horizontal and vertical forces.

If the resultant pressure should pass outside the middle third of the base, as at J, at one-third the length of the base from its centre C, then the total vertical pressure is crowded upon the leeward half only of the base C B, and consequently the mean unit pressure over the half base becomes double of the same total pressure when spread over the whole base. The maximum pressure B d (Fig. 27) equals twice the augmented pressure B e. The zero pressure is thus changed

from A to C, and there would be tension or up-lifting force at A equal to the downward force at B, making the structure unstable.

Uniform Distribution of Vertical Pressure.—When there is no wind-force acting upon the chimney, the pressure upon the foundation is uniform. The parallelogram A a, B b, represents the amount of that pressure, in which its intensity per unit area of foundation surface = the ordinate A a, which = the ordinates at all points along A B, and therefore the downward system of parallel forces or loads, and the upward parallel system of reactions balance each other. This may be indicated by the upward and downward arrows at C, being the resultants of the parallel forces which are placed opposite each other in the vertical line d'c of the centre of gravity of the rectangle A a, B b, and of the chimney. C is the position of the centre of the load pressure upon the soil. N is the centre of resultant of load pressure and the wind-force. When the central load pressure is in the geometrical centre of the base A B, there is no influencing wind-force, and the pressure is uniform along A B.

Eccentric Loads Act as a Static Couple.—If the resisting pressure of the soil (i.e., the reaction) is conceived to remain uniform and to act through its centre of pressure, C, in the direction of the upward arrow, and that the resultant of the loads and of the wind pressure act downward at the point N, they, being equal, parallel, and acting in opposite directions, form a static couple tending to rotate the arm of the couple round its centre. The moment of this couple is measured by the perpendicular leverage between the parallel lines of their direction \times one of the forces. The tendency of this couple in one direction is resisted by the opposing couple, made up of an increased resistance of the soil-base on the leeward moiety, and the decrease of the load pressure upon the windward half or moiety of the base.

Limiting the Pressure on Soils—Stability Against Unequal Settlements.—The maximum resultant

pressure exerted by the total loads upon the foundation soil at all points should be carefully proportioned by having a sufficient extension of the foundation base, so as not to exceed its safe unit-bearing power. The unit pressure should be uniform throughout the foundations of the same building. (See table of the usual loads in practice upon particular soils, p. 243, ante.)

It is evident from a consideration of the above demonstrated practical principle what a little deviation of the point of application of the resultant pressure from the centre of the breadth of the foundation base is sufficient to induce a disturbance more or less serious in its consequences when supported upon compressible soils. Thus a deviation of one-sixth of the breadth of the base from its geometrical centre is sufficient to bring a zero or vanishing pressure at the windward edge—i.e., on the longer arm of the base leverage, and double the unit pressure at the leeward side, assuming the base to be rigid. But if not, and that the transverse strength of the offsets of the footings be insufficient so that they break away, or are turned up on the edge, then even a less deviation may produce a dangerous disturbance, and thereby induce an extra increased unit pressure upon the soil underlying the leeward side of the base area thus reduced, so that the augmented pressure dangerously exceeds the safe unit-bearing power of the soil. It will thus be seen that a factor of safety of four at least in the bearing power of the soil should always be provided in exposed tall structures, and should be increased for structures of a permanent character.

Abutments of Bridge Arches, Counterforts, Buttresses, Retaining-Walls, &c.—In the above and such-like structures which are intended to resist oblique thrust, with more or less of a horizontal component that tends directly to overturn them, it is usual to have the resultant oblique thrust to intersect the footing base or any given bed-joint within the middle-third of their breadth in the line of the thrust. The

middle-third principle has been explained in the last article with reference to the position of the centre of vertical pressure. In the present instance it has reference to the centre of pressure in an oblique direction.

Blockwork.—Conditions of Stability.—In treating of the stability of such structures, they are considered under the conditions which determine the stability of "blockwork"—i.e., composed of a series of superimposed blocks or courses of bonded masonry. These conditions are deduced, from the action of (1) friction (2) position, and of (3) crushing resistance, as follows: 1. The obliquity of pressure should not exceed the angle of repose. 2. The ratio of deviation of centre of pressure from geometrical centre of joint to the length of its diameter in the line of deviation must not exceed $\frac{1}{3}$ to $\frac{2}{3}$, according to circumstances. 3. The stability against crushing of the blocks, or the crushing resistance, is included under "strength of materials." For crushing resistance of stones see p. 628, Vol. LXII. Both of these conditions of stability should be fulfilled at each plane or bed-joint of the structure. The known pressure in position, direction, and amount, acting upon the top joint of a block in a superimposed series of blocks, when combined with the weight of the block and any external force acting upon it, will give the entire resultant pressure at its bottom bed-joint, in intensity, direction, and position. This resultant will intersect the latter joint in the centre of pressure.

Buttress.—A buttress may be distinguished as masonry projecting from the front of a wall to increase its moment of stability. It is principally used to counteract the oblique thrust of roof trusses in Mediaeval edifices, as A, Fig. 31, a being the principal rafter whose axis will represent the line of action of the resultant of all forces abutting upon it above the joint with its template.

In Mediaeval buildings buttresses were introduced to resist the oblique thrust of vaulting and groining, in which cases the centre of oblique pressures will be discharged upon the abutment through the ribs of the groins or the voussoirs of the vault, and likewise those of the arch of a bridge.

If Fig. 32 be conceived to represent a part of a surbated vault, and b, c be a voussoir joint in the vaulting; then g, f represents the direction of its oblique thrust discharged upon the buttress C, B, A, J. If, however, Fig. 32 were the abutment of a bridge arch, then A, J would represent one of a series of counterforts between the wing walls, which retain the embankment and its slope.

Retaining Walls are intended to resist the thrust of abutting banks of earth, or rather the wedge-shape section of the earth lying above the slope of repose of the earth, which has a tendency to slide the wedge section, and thereby produce a horizontal displacement of the wall, either along the base or a bed-joint, or it may cause the top to overhang the base more or less according to the relation of the resultant of the thrusting and resisting forces involved. Owing to the prevalence of the tendency of earth thrust to slide a retaining wall in a horizontal direction either along its base or on a bed-joint, while retaining its vertical position, it is usual to incline the base, and when founded on clay, shale, or slippery soil to step and toe the base in the soil. The bed-joints of the courses of masonry are also inclined in a dip towards the bank, and likewise to give the face a better of a similar inclination from the vertical. [The present article does not contemplate the discussion of the theory of retaining walls.]

Pilaster is a shallower projection of masonry than a buttress, and is intended to serve a different purpose to the foregoing—i.e., to increase the compressive wall area at the distributive points of heavy loading, and likewise to stiffen the wall against buckling in its height. The strength of pilasters is governed by the same principles as determine that of slender pillars, which the limits of the present article do not admit of discussing.

Buttressed Retaining Walls for Cellars.—Retaining-walls are sometimes composed of buttresses, with a system of bay archings between them in a vertical plane. For deep cellar or basement and area walls they are economical of materials, when the buttresses also act as the supporting pillars of the superstructure, whose weight becomes the counterloading to the horizontal thrust of the earth. The arched bay has

no footing, so as to avoid unequal settlement; but is supported by an arch ring, springing from the pier footings.

Oblique Abutting Force.—In order to compute the stability of a structure against an oblique force, it is necessary to know the amount, position, and direction of that force. As a simple illustration, suppose that in order to compute the sufficiency of an abutment against the oblique thrust of an arch and spandrel, its amount, position, and direction are required.

Thrust of Arches, Vaults, and Groins.—Assuming the half-arch and spandrel (*a c d e*, Fig. 32) to act as one rigid mass upon the skewback *b e*, the amount of thrust can be obtained by the principle of moments of its centre of gravity about the centre of the skew joint. [The centre of gravity can be found by suspending its shape *a b c d e* drawn to scale, and cut out of cardboard, from the ends of two diameters normal to each other, the intersection of these diameters will be the centre of gravity of the shape]. Assume that the centre of gravity is at *g*, through it draw a vertical line *g w*, then from the centre of the key-stone joint *h* draw a horizontal line intersecting the vertical in the point *g*. This line *h g* represents the direction of the horizontal pressure exerted by the opposite half-arch and spandrel, which holds the halves of the arch in equilibrium against each other. From the point of intersection *g* draw a line to the centre of the skewback joint *f*, and produce it indefinitely down the abutment. From the point *g* measure down the vertical *g w* equal weight of the half-arch and spandrel. From *w* draw a horizontal line intersecting *f g* in the point *f*. Then *w f* by the same scale is the measure of the horizontal thrust, and *g f* of the oblique thrust—i.e., the resultant of the vertical and horizontal forces, and also its direction at the joint of the skewback, tending to overturn the abutment or to slide it along some of its bed-joints.

Stability against Overturning.—As the weight of the abutment reinforces its stability, the value of this above the base or any joint whose stability is to be checked, is to be ascertained as well as its centre of gravity. Draw a vertical through this centre of gravity of the portion *a J K c*, above the bed-joints *J K*, intersecting the line of oblique thrust in the point *n*. From *n* measure off *n o = g f* the amount of the thrust by scale, and from *n* measure *n p =* the weight of the portion of the abutment above the joint *J K*, and complete the parallelogram *n o f' p* and draw the diagonal *n f'*, which gives the direction of the resultant of the arch-thrust and the weight of abutment above *J K*, and which intersects it at a point within the middle third.

Similarly we might find the direction of the resultant of the weight of the whole abutment above the base *A B* and the point of its intersecting the base. The extension of the diagonal *n f'* however intersects the base within the middle third.

Stability against Sliding.—Having now obtained satisfactory proof that the abutment is stable against overturning, it must next be ascertained if the bed-joints are safe against sliding. For this purpose measure the angle which the normal to the joint makes with the resultant at the joint. The natural tangent of this angle is the coefficient of friction. If, now, the coefficient of friction of the masonry employed be obtained from the table at p. 801 ante, and we find that it is not exceeded by the natural tangent of the measured angle, the bed-joint is safe against sliding by the effort of the oblique thrust.

If the measured angle with the normal were greater than the angle of repose of the masonry, the abutment above the joint would slide and be unsafe.

Friction a Factor of Weight.—Since the coefficient of friction is a factor of the weight pressing on the joint, the remedy must either be (1) an addition to the weight, or (2) by inclining the bed-joint so that its normal would make a less angle with the resultant thrust—i.e., would be more nearly perpendicular to the bed-joint.

Inclined Bed-joints.—Thus the joint *J K* might be inclined to *J l*, so that its normal would make a less angle with line of thrust. The most notable examples of the application of the (1) expedient are the pinnacles surmounting the buttresses in Mediæval edifices. (See Fig. 31.) Examples are also found in engineering structures, such as frequently may be introduced on retaining walls. Thus the terminal pillar of the

wing wall of an embanked road bridge at Edinburgh, westward of the castle, is surmounted by a high pyramid, because of confined space, which did not admit of a lateral extension equivalent to the moment of stability required.

Thrust of Roof Trusses, Struts, or Framework.—By a similar procedure to that already described with regard to the resolution of the forces, illustrated by Fig. 32, the thrusting forces acting along the axis *a* of the principal rafter of a roof truss, or of a strut, or a converging point of framework (Fig. 31), and the resisting forces of the pinnacled buttress *c A B b* can be resolved. Then from the intersection of a vertical passing the centre of gravity of the buttress and pinnacle above the bed-joint *c b*, with the oblique force *a g f* lay off *g f' =* to that force by a convenient scale, and from the same intersection point *g* lay off *g w =* weight of buttress and pinnacle above the joint *c b*. Then complete the parallelogram *f f' w*, and draw its diagonal *g f'* to intersect the joint *c b*. If this intersection be not within the middle third of the joint, then increase the weight of the pinnacle by extending its height. Suppose the increased weight to be represented by the arrow extension, then complete the parallelogram *g f' w*, and draw its diagonal *g f''* intersecting the lower joint in *f''*, which is within the middle third. The joint has also been proved safe by friction against horizontal sliding, as already explained.

CYLINDERS AND TANKS FOR HOT-WATER WORKS.

THERE is inquiry very commonly made as to the particular uses of these two kinds of hot-water reservoirs, and as to why one shape is used instead of the other. In other words, it is asked—Is there actual need for these two distinct shapes, and why one or the other will not do in all cases?

This question does not emanate from a skilled hot-water engineer, of course; but it does not follow that it comes from one totally ignorant of the work. There are many very capable of erecting an apparatus upon the older "tank system" who are not conversant or had experience with the more modern cylinder arrangement, and the question from such is not an unreasonable one. It is not only the builder, who having a limited number of hot-water jobs cannot keep pace with the times, but the architectural profession has frequently to fall behind if their works do not often touch upon undertakings of this kind.

The two articles in question are here shown—Fig. 1, the tank; and Fig. 2, the cylinder. With the older form of hot-water apparatus the former was invariably used, and generally situated up in the roof of the residence, or, at any rate, it was placed above the highest draw-off tap. This high position made it eminently adapted for its purpose, as, being so near to the supply of cold water, it had but little pressure to withstand internally. With the "cylinder system" of apparatus, which is of a more modern plan, the hot-water reservoir or tank is placed close down beside the boiler or kitchen range, and therefore a considerable distance below the cold-water cistern, which is at the house-top. This distance necessitates a high pressure or strain being exerted inside the tank, and if of square shape there is every possibility of its bursting, or some joints giving way at least, when it is charged with water. With this latter system a cylindrical-shaped tank or reservoir (usually called a cylinder) is almost invariably needed, and it has given the distinctive name to the system. It is quite possible to carry out the "cylinder system" of hot-water works with a square tank as the reservoir, provided this latter article is capable of withstanding the pressure. Figs. 3 and 4 show the tank and cylinder systems respectively in a simple form.

This pressure of water from the cold-water cistern to the hot-water reservoir is not as much understood as it might be, yet the knowledge is very essential in carrying out hot-water works of any kind. When an apparatus is erected upon the cylinder system, with the cylinder, say, 30ft. below the cold-water cistern, there is a pressure of 13lb. upon every square inch of surface within this cylinder, which upon a rough computation represents a total aggregate pressure upon the interior surface of about 10 tons. If we put a square tank in such a position it would bulge out and endeavour to assume a spherical shape, and this means injury and leakage. The pressure of

water in pipes is 1lb. for every 2ft. 4in. in height. In other words, a pipe 2ft. 4in. in height and lin. square (inside measurement) holds a pound weight of water. It will be seen, therefore, that if there is 30ft. vertical distance between the cold-water cistern and the cylinder or tank, the pressure exerted in the latter is 13lb. per square inch as just stated. There is a notion that the fact of its being a hot-water apparatus lends to this strain or pressure, but this idea is fallacious, as the exertion is due to mere weight of water, and, whether hot or cold, is the same. In the illustrations, 3 and 4, it will be seen upon a little reflection that as regards the phenomena of pressure, &c., it is simplicity itself. Water flows down a pipe from the cold-water cistern, and after filling all the pipes and vessels below, it finds its own level in the pipe that extends up to above the level of the cistern in question. The strain upon the reservoir, boilers, &c., below is, therefore, the mere weight of water pressing down these pipes, 1lb. for every 2ft. 4in. vertical measurement. It is only vertical measurement that counts; horizontal pipes are inert, and sloping pipes are active only as regards the difference in height of their opposite ends.

The utility of cylinder and tank then amounts to their ability to withstand the pressure, the former better than the latter. This might lead to its being asked why cylinders, the superior pressure-resisting reservoirs, are not used always. The reasons are two: first, that the cylindrical shape occupies more room than a square or rectangular tank of equal capacity; secondly, cylinders are the more expensive. The difference in expense is considerable when we take a cylinder and tank of equal thickness of metal; but if we ignore the thickness of plate, and compare the pressure-resisting powers, the expense is reversed. It must be borne in mind that although consideration for pressure is requisite, and of primary importance, it does not follow that a reservoir of just exact strength be used always, and if good work is required, a better quality than the mere pressure calls for should be used. For instance, a cylinder of very light metal would be equal to 25ft. pressure; in fact, one of stout sheet tin would bear it; but how long would such a flimsy thing last? All tanks and cylinders should be used at least one quality greater than the bare pressure necessitates, as such articles should be capable of continuing their work efficiently for several years. A well-known tank-maker's list gives tested pressures as follows:—

Galvanised Rectangular H.W. Tanks.

Tested to, per square inch:—

16 gauge.	14 gauge.	12 gauge.	$\frac{1}{2}$ plate.	$\frac{3}{4}$ plate.
11lb.	31b.	41b.	51b.	101b.

Galvanised Cylindrical H.W. Tanks.

Tested to, per square inch:—

16 gauge.	14 gauge.	12 gauge.	$\frac{1}{2}$ plate.	$\frac{3}{4}$ plate.
51b.	151b.	201b.	251b.	401b.

Now tested pressures do not mean the utmost limit of pressure when leakage commences. It would be possible to put them to work greater than the tested pressures, and to do it effectually; but the practice is not commendable, as just stated, and really should not be thought of.

The square or rectangular tanks are almost invariably made with manholes and lids; but cylinders are not always so provided. With these latter the list says: "With manhole and cover, or loose bolted top, £4 5s." (the price of a certain size); "without manhole or loose top, £3 18s." By this we see that putting a manhole and cover, or a loose bolted top, costs on an average 7s.—that is to say, if the cylinder is ordered without these conveniences, and is supplied with a fast riveted top, and without any means of access to the interior, the price is 7s. less than otherwise. Now, a lid is not an absolute necessity with either, if flanges are provided at the points where the pipes have to be connected. If we connect a tank, as Fig. 5, and a cylinder, as Fig. 6, it will be seen that no part of the work takes place inside, as the flanges (which are attached outside) permit of the pipes being securely jointed into their substances. Tanks and cylinders never really require to be opened for cleaning or any other purpose after they are once fixed. No hurtful accumulation of hard deposit occurs within them, and any dirt matter can be flushed out.

It is not particularly recommended to use either of these articles without lids or means of access to the interiors; but it will be seen that such a

thing is quite possible and practical. One very common way of connecting the pipes is as Figs. 7 and 8. When done in this manner, access to the interior is absolutely necessary, otherwise the interior connections, the stand-pipes shown, could not be attached.

Reverting to the pressure of water again, there is one question, which is occasionally looked upon somewhat as a problem, that might be explained. This is the fact that the pressure in cylinder or tank is precisely the same whatever sized pipe be used, and independently of the size or shape of the cold-water cistern. To calculate the pressure accurately, it is the water level in the cistern that has to be taken as the highest point, and the area or contents of the cistern make no difference. In speaking of the pressure, it was explained that a pipe 2ft. 4½in. (nearly exact) in height and with an internal area of 1sq.in. would hold 1lb. of water. If such a pipe was stood on end and filled with water, its contents (the water) would be pressing down upon whatever supported it, with a pressure or weight of 1lb. If the pipe were twice as high the pressure would be 2lb., and so on in exact increase or decrease as the pipe was higher or lower. If instead of the pipe being one square inch internal area, it was only half this size, its contents would only be ½lb. every 2ft. 4½in., and the pressure on its lower extremity only ½lb. This sounds as if the pressure decreased with the size of the pipe, but it does not, for this less weight only presses on half of a square inch area. Therefore, if a cylinder be fed by a pipe of this size, the pressure internally would be ½lb. upon every half a square inch surface, and a moment's thought shows that this is exactly equal to 1lb. upon each square inch. The same rule applies if we use a larger pipe: the pressure remains the same. A pipe of 2in. causes a pressure of 2lb. (for every 2ft. 4½in. of its height) upon 2in. of surface. The very common and handy way of calculating pressure is to ascertain the vertical distance between the cistern and cylinder, and then allow ½lb. for every foot in height. It is not exact, but it errs on the right side.

Upon this reasoning it will be seen that the size of the cistern makes no difference, provided the water level is constant. If it were possible to continue the cistern in its entire size down to the cylinder or tank, it will be seen that the pressure of water in this latter article would not vary. There is advantage in having large cisterns and large pipes in the fact that the former insure an abundant supply, and the latter a free flow of water. A small pipe means a slow flow of water, unless the tap be at the bottom of the house. At a bath which is not usually at the bottom level, a sluggish passage of water is an annoyance. The same at a lavatory, or anywhere, in fact.

No hot-water tank or cylinder should be left without covering of some kind to prevent loss of heat. It is occasionally permissible when its radiated warmth is needed for a useful purpose; but let it be clearly understood that whatever heat is radiated is lost from the water—that is to say, the water is lessened in temperature accordingly. It is astonishing what a lot of heat can be transferred from the water in this way when the tank is in a cold roof, and the pipes are in cold situations also. When a tank is in a cold place it loses heat faster than if in a warm situation, and as the object of an apparatus is to furnish water with heat in it, it seems unreasonable to let it be robbed of heat in this way. It is particularly unreasonable, and the reverse of economical, when the radiated heat fulfils no useful purpose whatever.

If we cover a tank with some poor heat conducting material we shall get hot water in less time, keep it hot with less fuel and attention, and, what is a particular advantage, the contents of the tank keep warm all night. This latter is an immense advantage, as it goes far to solve that ever-present problem, how to get hot water the first thing in the morning directly after the fire is lighted. The want of hot water is always most keenly felt in the morning. Most bathing takes place at this time, but as a rule, and chiefly owing to loss of heat by radiation, this is a time in the day when hot water is usually hard to obtain. If we well cover an apparatus with a poor heat-conducting material, we give the boiler every opportunity of doing its work effectually. In addition to this, there will be a noticeable economy of fuel, and if the fire is even allowed to go down for a little while, the heat of the water will not follow its example. The

temperature does not perceptibly fluctuate with the fire.

There are several materials suited for this purpose, all reasonable in cost; but even an old piece or two of felt carpet is not to be despised if the tank is in the roof and appearances of no importance. The nature of the materials must be such that they fulfil the purpose an overcoat does to its wearer; it resists the free passage or radiation of heat. Anything of the nature of felt is suitable, but doubtless hair-felt is the best of these. It being made up in sheets facilitates its application, and its edges can be neatly sewn together. It is made in various ordinary thicknesses from 3-16in. to ½in. The latter is the least that should be used in a single thickness. Properly speaking, the total thickness should be 1in. to fulfil its purpose effectually. Any less thickness means a less effective barrier to waste of heat. A single ½in. thickness is sometimes used, and it does some good, but to say it conserves the heat perfectly is incorrect. To do the

really perfectly, even a 1in. thickness is insufficient. The idea is very common that a single thin sheet of felt suffices, and it does in a limited way; but the thicker application well repays the expense.

As some people have an impression that hair felt is favourable to insect life, it is not always used. There is no other substance so convenient for wrapping round an article as this blanket-like material; but where it is convenient, the tank may be incased with wood, and the space between the metal and woodwork filled in with sawdust or sand. This is very effective, as wood is a very poor conductor of heat. Doubtless, the best material to fill in wood casings is silicite cotton. This material stands high in favour where heat is to be resisted or imprisoned. It is very clean, reasonable in cost, and, provided there is a casing, it is easy of application. It can now be obtained secured on to strips of canvas, which makes it convenient for wrapping purposes. In appearance and texture this mate-

rial is almost precisely like cotton-wool; but it is non-inflammable, consisting, as it does, of silica or glass. Any simple experiment will prove the extremely poor heat-conducting properties of glass.

When a tank or cylinder is placed in a cupboard or casing, and not packed round with any material, there usually appear black puff-like marks against the walls or ceiling where the joints or crevices in the woodwork are. These marks also appear, although not so distinct or defined, above tanks, and also pipes, that are totally uncovered. Inquiry has more than once been made in this paper, and also in the *English Mechanic*, as to the cause of these marks and the remedy or preventive. The cause is easily explained, and is as easily prevented, as the trouble is wholly due to an up-current of air being created by the heated surfaces. This phenomenon might be adduced in evidence of the rapid way tanks and pipes are robbed of heat when unprotected, or in cases devoid of packing material. As explained earlier in this paper, the atmosphere, when it comes in contact with a heated surface is rarefied and caused to take an upward direction, and this up-current is very rapid indeed. (The rapidity is far greater than would be thought without experience of it.) This heated air makes its escape if in a cupboard, from whatever crevices or openings it can find at the top, and in its rapid escape there it impinges upon any surface that may be near. The action is of the nature of a mild blast, and as the air always has particles of dust and impurities suspended in it, a dirty mark ensues. It will be understood that it is not the air that causes the mark referred to, but the dirt particles that are carried in it, and impelled or thrown against the surface.

The remedy is, of course, to prevent the air being rarefied, and to do this it must not have contact with a heated surface. This is effected by covering the tank as recently explained; but as many people put a tank in a cupboard purposely to make an airing-closet for linen, this remedy will not always do. In such an instance effort must be made to perfect the joinery so that no crevices exists; but here we have an enemy in the heat itself, which distorts or shrinks the best of woodwork. After all, there is scarcely anything better for crevices of this kind than common glazier's putty, which behaves well under heat. After the woodwork has well shrunk, stop the crevices with this material, which will endure and answer well if no further shrinkage takes place. If the heat from the tank is not required for a useful purpose, then it should be well covered, and the crevices stopped as well.

A much-disputed point relating to tanks and cylinders is the question of responsibility when one of these articles of good quality leaks after, say, two years' use. They should last in good order longer than this, and in such a case it is not that the tank is worn out, but has a small leakage from a minute pinhole at one point. Examination inside shows that it is only this one spot that is affected, and the total area of the affected part is perhaps only the size of a sixpence, or less. Such a place can be repaired with a soldering iron, provided it is in an accessible position, and in such a case no one would make any trouble about it, although it means half a day's work for a skilled man. When, however, the leakage appears in an awkward spot, and the tank or cylinder has to come down with the work necessary in disconnecting and reconnecting, it makes the hot-water engineer consider whether the responsibility is really his, and then the question arises as to who is liable. It has never to the writer's knowledge been satisfactorily settled as to what is the cause of these little weak spots. The tank-maker is apt to argue that some acid or salt in the water is to be blamed, and this being the case, it relieves him. It is to be feared, however, that the nature of the water is not accountable for the trouble, or, at least, not wholly so, for why is it that only one little spot is affected? It is most probable that the real fact of the matter lies in there being a weak spot in the plate, possibly a point that the galvanising fluid has not acted upon, due to a scale or cinder. It is a difficult point to decide. If the fault showed itself in a few weeks, or even months, the hot-water engineer would probably consider the blame his; but when it is a couple of years, he very naturally feels that he should be relieved of blame, and so the matter ends in an unsatisfactory

way between tradesman and client. If anyone can speak authoritatively on this point, a discussion would be of much utility generally.

The last point to mention, but not the least important one, is as to the size of hot-water reservoirs, tanks, or cylinders. There is a mistaken notion that a large tank (or cylinder) means an ample supply of hot water. This line of argument sounds as if the increased size of the reservoir added by some means to the heating power of the boiler. Engineers with modern ideas are using small tanks and cylinders, not only because they are less expensive, but more efficient and generally agreeable results are attained.

When we use a large reservoir (meaning tank or cylinder), we certainly have a greater bulk of hot water at demand when once it is hot; but this waiting for it to get heated is the great difficulty. It means about three hours in the morning as a rule, unless every possible precaution be taken, and then when at command it is practically useless; the bathing hour is past, and unless the residence be on a large scale, or it be an institution, the large quantity of hot water is never required. What is meant by a large reservoir is one holding, say, 60 gallons—a size commonly used where a 40-gallon would do far better. If a house has one bathroom and two other taps, and there are, say, two or possibly three servants, then a 30-gallon reservoir will suffice. With a larger demand the size is increased proportionately; but if there were two baths, both used at once, and four other taps and a fairly large household, a 52-gallon reservoir would be large enough, and this would need a boot-boiler in a 12in. fire to work it properly.

The advantage of a small reservoir is that results are obtained much quicker under any circumstances. A 35 to 40 gallon size is sufficient for two baths at once, as its contents will probably be scalding hot. Then in a case of bath succeeding bath, the small reservoir has its contents heated up in such short time that it is ready for each succeeding bather, assuming a bath takes twenty minutes. Of course, the first cost is less with the small reservoir, yet the lessened cost does not mean lessened efficiency.

"BUILDING NEWS" DESIGNING CLUB.

LOCAL BOARD OFFICES FOR A VILLAGE.

THIS is a good practical subject, and useful enough when County Council work is developing and Village Councils are talked about. Local Board Offices hitherto, as a rule, have been miserably housed for the most part, and more than often either the offices have been erected without an architect, from builder's plans, or the road surveyor has been engaged to prepare a "design." The problem is an attractive one to the young architect, as affording sufficient scope for inventive fancy without too much trouble; but we are bound to say that out of all the very large number of plans sent in for our first competition in this term of our Designing Club, not one realises exactly what may be called a model type of design. We should do our contributors an injustice if we over-estimated their productions, and while we are constrained to take exception to many of their designs, we are fully alive to the industry and care with which they have done their work. The following were the conditions issued for the guidance of competitors:

A.—Local Board Offices for a country village in a stone district. Site to be an isolated one facing west, with a road frontage on front and right-hand only. Accommodation to comprise office for surveyor, with drawing-office for one clerk. A pair of rooms for the clerk to the local board, one being his public office for inquiries. A rate collector's office and a board-room for ten members, who will sit at a horse-shoe table. W.C.'s and lavatory to be provided, and a caretaker's residence, consisting of living-room, scullery, pantry, w.c., and two bedrooms. The size of the rooms is left to competitors. The board-room to be on the first floor, with the rooms of the clerk to the board. A strong room, 6ft. square, for his use to be provided. Caretaker's door to be at the rear of the premises, and his rooms may be on two floors at the back. Scale 8ft. to the inch. View, two elevations, section, and plan. Plans may be drawn to 16ft. to the inch, if necessary.

"Huguenot" is placed first, "B. gyn. R." comes second, and "Cantab" ranks third. "Clarence" is fourth, and "Kelpie" fifth.

We illustrate the first two designs herewith, and the drawings speak for themselves. It is a curious coincidence that both plans project over the public footway in front of the building, and this is a great objection where public convenience is considered at once, obstructing the pavement, and causing nooks and corners for nuisances to occur. Most of the designs were free from this objection; but still the plans chosen, taking one thing with another, are the best. Architecturally, "Huguenot's" design is dignified by a commendable simplicity, and the bands of coloured stonework serve to bind the composition together, though it is lacking rather in sufficient dignity of appearance outside to suggest its public character. The entrance-door is not important enough, neither is it particularly convenient for general use. The plan is better with the caretaker's residence nicely isolated, and yet readily accessible. Some of the plans are exceedingly faulty in this respect. The surveyor's drawing-office faces north, and the surveyor can get at his room without always passing his assistants. We hardly like the board-room, which is too narrow, and the strong-room cannot be rightly so described, with its match-like front, indeed, it is only an ordinary cupboard, very inconveniently situated. "B. gyn. R." commences well, and endeavours to break away from the regulation hum-drum, "appropriate" type of work. The projection into the street is a mistake as here shown. A forecourt in front of the rate-collector's office would modify the objection by setting the building back! The space occupied by the staircase seems needlessly extensive in so limited a building, and neither the surveyor's nor vestry-clerk's offices look particularly comfortable. The window, too, which lights the hall staircase is insufficient in extent, and being placed in the corner as it is, the window would look one-sided and badly managed. The entrance to the caretaker's house from the offices being through the lavatory, the privacy of the w.c. is destroyed, and in other ways the arrangement is most objectionable, particularly for the woman passing to and from her duties of cleaning the offices. The chairman's room is a mere ante to the superior w.c. The strong-room is located over the front door. "Cantab" gives us perhaps the most sensible elevation of the whole series, and we really like his architecture for its quietness and reflex of old Jacobean English work, inspiring his design with an official character, with well-balanced fenestration and quaint plain gables. His drawings lack crispness, and his perspective, through truthful, is poorly done. The plan does not equal the merit of the elevations, though it is well lighted and straightforward. The chairman so close to the board-room fire would risk a roasting occasionally, and the offices for the clerks and collector do not look comfortably arranged. "Clarence" adopts the style of building with a portico entry, rusticated ground-floor stage and pilasters over, carried up at the angles supporting the cornice all round in a sort of Bath stone and Kentish rag recognised treatment. His plan, however, is very practical and well arranged in so far as its general contrivance is concerned. His drawing-office faces west, however, and the lavatories are too intimately connected with the caretaker's wing to be really nicely managed. A second office is given to the collector, which is hardly necessary, and was not asked for. This design is much more the sort of thing which the ordinary local board member would vote for. Its spacious rooms recommend it, though the local ratepayers would find it expensive. The canted way to the lavatory upstairs cut out of the board-room is a bungle for "Clarence," and being off the quarter landing, would appear as a bulk-head in the council chamber. A false one on the other side makes the balance true. "Kelpie" is a bad planner if this design ranks as a fair specimen of his work. We regret this, as his elevations show taste and a certain sense of fitness. The straight dark passage connecting the main doorway with the caretaker's living-room is ugly, and an interior area to so small a structure, one would think, was needless. The surveyor's office has no north light, and his clerk-room is too small for a drawing-office. The clerk's own apartment is an uncomfortable little place, all window, doors, and fireplace, opening only through either the board-room or clerk's office. The pent over the entrance seems perched up awkwardly. "Lochgill" sends a sensible sort of design, having much to commend it; but the numberless windows give a hospital-ward effect. The

plan, without waste of room, is spacious and convenient, though the caretaker should have had a better entrance to his house than through the scullery. His only other outlet is by way of the office entrance, which is not always convenient. The drawings of this design are well arranged and neatly done. A little more spirit infused into the composition would have enabled us to place it higher. This doubtless "Lochgill" will give us a chance of doing another time. "Dunottar" forwards a commonplace design; but he has, by quaintly grouping pilasters along the façades, imparted a somewhat fresh character, and enhanced the expense. The surveyor is put facing south, which upsets the north light for the drawing-office. The staircase is more reasonable in scale, and the ante-room to the board-room gives a little space for members' hats and cloaks behind the grand columns, for there is no other cloak-room accommodation. The two first designs do give some convenience in this respect. "Ecosse" is a compact and neat planner, though he does not sufficiently consider relative values. His Jacobean sort of design looks crude and wanting in refinement. The plan shows a drawing-office facing east, a hall which would not be too light, and a caretaker's house which could not be reckoned upon for comfort. The extreme care displayed by these drawings indicates unmistakably that "Ecosse" means to do his best and improve. He draws neatly and prints well. "Black Diamond" makes a pretty elevation, looking more like a comfortable tavern with its row of four gables in timber work. The suggested detail is refined and marked by study, but the plan does not harmonise nicely with the external treatment, with the thin division walls coming anyhow, and necessarily, therefore, mostly in timber quarterings. The arrangements, too, are crude, which is a pity while "Black Diamond" has so appreciative a sense of proportion in his façades. His perspective is weak and thinly delineated. "Offside" makes his long side of the building face west, bringing a bay window out into the pavement. The façade is prettily managed, but there is a great waste of space in the entrance hall and landing over it. "Offside" will do better than this. "Shylock" ("be not too shy!") puts his motto so small in the curve of a scroll, that we could scarcely find it. This design is intended to be "Classic," and has good points in the plan, but the bad ones predominate. The awkward starting to the curved staircase fitting in a square angle is enough to condemn any plan. "Classic" is the motto of the next design, which in style is more free German Renaissance quaintly managed, ingeniously contrived, but terribly crowded, both on plan as well as elevation. "Classic" merits praise for an endeavour at originality. "Rex Tab" has a rough-cast upper stage and a speech closet (it is called a "gallery") leading to a little balcony over the main entrance, a fitting place from whence to address the "free and independent" or the "unemployed," as circumstances might dictate. The drawings are neat, but this plan, though spacious, is wasteful, with rooms of ugly proportions. The detail suggested by the elevations shows that "Rex Tab" has studied good work. The hall, depending on a small roof glazing, would be not light enough. "Red Lion" thinks the ponderous Georgian style most suitable, and to avoid its looking too formal, draws his perspective in the "flick and dot" manner, to give it an airy appearance. We rather like his essay, but do not see where the top light, on which the hall and staircase depend, comes in. A sloping casement would cut into the valley made by the rear roof intersecting that of the main building. The surveyor's office faces south. "Baboo" has rather pretty Old English-looking elevations, carefully drawn. "Ecco, Fatto" falsifies his design in his view of it. "The Idler" draws coarsely, and is untidy, but has a sense of quaint design of the better sort. He ought really to do better. "North Wind" nearly scores, and is not afraid of plain walling, which always looks well, but his plan is wasteful. "Ben" is sketchy, and makes a sensible-looking building, but his knocked-off plan is wanting in study. Thus the space for the "public" behind the chairman in the board-room would never do. The regulation malcontent ratepayer in such a position would be worse than the fireplace in "Cantab's" design. "Spare Moments" prepares a half-timber design, with a spire at the angle over a corbelled tower bay, which comes inconveniently

Fig. 14 Source of light before the observer.

out of the staircase. The plan has merits, but the elevations look more suited to a free library. "Tit Willow's" design is overdone, and the drawing-office faces S.W. "Triangle's" elevation, with its conical roof, would group well, and the oriel windows seem suitable. The plan is consumed with corridor space, which is enlivened with w.c.'s opening out of it publicly. "Cyclist's" plan is economical, and marked by a plain tower outside; it is drawn to resemble a villa of the pattern-book kind. "Hardwick" has a pretty side elevation copied from some old work, probably in Northants; but the front does not accord well with it, while the plan has to be managed to fit into the bays. "Heather" comes next with an inky perspective, and then "Signor McStinger," with a squat tower projecting on to the public path, and inclosing the main staircase. "Farnden" adds a circular tower of Scotch variety. "Compact" is the motto of a design extended to double the width of its competitors. "E. T. I." is severe Queen Anne, which actually would look far better than the drawings allow, for they are miserably poor and scratchy. "Hug" makes his elevations too much like a board school, but his drawings are exceedingly neat. The drawing-office faces west. "Carlos" does the same, and "Cleopatra," with a freedom of idea, makes his elevations look high-shouldered. He should make an advance upon this effort. "L" in a circle puts a double bay quaintly in front of his building to mark the staircase.

The following are the mottoes of the remaining designs in their order of merit:—"Aliquis," "The Odd Man," "Benihassan," "Grace," "Big Ben," "Bobadil," "Mysorum Ultimus," "Wacota," "Bos," "La Crosse," "Symple Symone," "Royerus," "Sigurd the Viking" (Cardiff), "Wyandotte," "X. Y. Z.," "Hopeful," "Sweet Auburn," "Arnaud," "Sigurd the Viking" (Swansea), "Mosquito," "Perseverance," "May," "Parabola," "Nero," "Young Architect," "Veritas Vincit," "Signorenia," "Toreador," "Wigwam," "Cigarette," "Tyro," "Lulworth," "Me," "Edelweiss," "Vril," "La Cigale," "Jim," "Spero," "Rex," "Lotus," "What Mergorem," "Caenabo," "Ajax," "Ares," "Kohi-

noor," "Durability," and "Mac." "Duke" and "Billy" came in too late, but neither merit special comment; and "Duke," regardless of rules, sends in three sheets of paper of various sizes.

SHADOWS IN PERSPECTIVE.—VII.

THE rays of light still come from before the observer, and from any point in the sky, where we suppose the source of light to be situated. In the last example we studied the shadows thrown by vertical or horizontal planes against other vertical or horizontal planes. In the present example (Fig. 14) we will construct the shadows thrown by oblique and vertical planes, such as those of a chimney or dormer, against the sloping plane of a roof. The student should now be able to construct the ordinary shadows thrown by vertical and horizontal planes. If he has carefully followed the rules, and well understood the reasoning, he should find little difficulty in understanding the construction of the shadows in Fig. 14, which are most important.

In the last example the drawing was in parallel perspective. Fig. 14 is in ordinary perspective with the vanishing points. The drawing appears slightly distorted, for, in order to have at least one of the vanishing points within the figure, to explain the constructional lines, it was necessary to make the perspective very short. The vanishing point V1 should be much more to the left, and the point indicating the source of light, S1, should be placed at a larger distance to the left of point V, in order to obtain well-proportioned shadows. The placing of these points is, of course, a question of habit and good taste, and depends on the effect desired and the general mass of the architecture. The drawing is kept very simple in order to better explain the working.

The vanishing point of the large roof is at V1 on the horizontal line, the other vanishing point being in the direction V3 to the right of the drawing. The sun, or source of light, we will place at S, its projection on the horizontal line being at S1. The vertical projection of the vanishing point V1 will be at V on the line drawn from S to the vanishing point V3. The

reason and position of this point V was explained in the last article. We will first find the shadow thrown by the small chimney KM against the descending slope of the small roof. The angle of this roof gives us for its aerial vanishing point the point V2 on the line projecting V1, and the corresponding point on the line projecting point S is at S2 on the line from the vanishing point V3 through V2. If the roof was horizontal, we should, as in previous examples, use the point S1 on the horizontal plane for constructing the lower lines of the shadow; but as the roof makes an angle with the horizontal plane, we have to use the point S2 on the continuation of this plane for the constructional lines. It is easy to see that the plane S, k1, S2, containing the rays of light, and passing by the vertical line of the chimney KM, rests on the roof plane on the line k1; k1 is therefore the shadow line of KM. The same plane or lines from S and S1 passed through Oo and Mm will give us the line Oo1, the shadow line of Oo, and m1 the shadow point of point M. The shadow of the chimney is, therefore, contained by the lines O, o1, m1, k1, k.

Let us now find the shadows cast against the large roof plane. We take the chimney Dd. The constructional method is similar to that employed for parallel rays in Figs. 10 and 11—that is to say, we find the plane dyx perpendicular to the roof lines, and a continuation of the plane dDe, and by means of lines from y and x to the points V1 and S1 meeting at z, obtain the plane dyz in the plane of the rays of light; the continuation of zd to d1, where it meets the light line from S, passing through point D, gives us dd1, the shadow line of Dd. The student should refer back to Figs. 10 and 11, where this construction is explained. But as this process would be tedious, and necessitate too many constructional lines if the shadows were numerous, we will employ a simpler method of obtaining the shadow lines of vertical objects by means of one given point, and thus insure rapidity and correctness in putting in the shadows. The aerial vanishing point of the smaller roof we know to be at point V2 and S2 on the vertical from the source of light. S2 is the point from which we have drawn the shadow lines of the chimney KM.

In a similar manner, the aerial vanishing point of the larger roof will be on the vertical line projecting the second vanishing point V 3, and its height will depend on the angle given to the slope of the roof. All the upward lines of the roof, such as $ab, de, xx, ii, &c.$, should converge to a given point on the line projecting vertically the vanishing point V 3—that is, in the direction V 4. This point is outside the limits of the drawing. Given the slope of the roof, if we suppose the roof to be continued as far as its vanishing point, V 1, the angle of the roof at this point would be represented by the line V 1, V 4, or the line joining the vanishing point V 1 and the aerial vanishing point V 4. If we produce this line until it meets the line S, S 1 produced, we obtain the point X and the plane S, X, V 4 containing the rays of light. If now we revolve this plane S, X, V 4 about its axis SX, the line XV 4 will pass along the surface of the roof, and by its means we may determine the shadow lines of the vertical lines of the chimneys P, exactly as for shadows on the ground plane, we use the point S 1, situated on the ground plane, as point X is situated on the plane of the roof produced; therefore, to obtain the shadow lines of Aa, Bb, Cc , we pass lines by the lower points a, b, c from the point X, and determine their length by means of the light lines from S passing through the upper points A, B, C. Similarly, we find $d, d 1$ the shadow line of D d: likewise $e 1$ the shadow point of a point E; the line joining $d 1, e 1$ produced is the shadow line of DE. This construction is correct, for we obtain the same shadow as with the construction dyz . Point w is obtained in a similar manner, and wx joined gives us the shadow of Wx. The shadow of the large dormer Gg is obtained by means of the line from X passing through the lower point G, and its intersection with the light line from S through G, giving us $g 1$ as the shadow of G; $g 1, g$ will, of course, be the shadow line of Gg. The line joining $g 1$ and the point k gives us the shadow of Gk, a portion only of which is thrown against the roof.

But we will notice that the shadows of all the horizontal lines of the chimneys and dormers converge to a certain point, the lines $f 1, f; a 1, b 1; d 1, e 1; g 1, g, &c.$, all converge to a point T on the line joining S and the vanishing point V 3; therefore, by means of these two points, X and T, we may obtain nearly all the shadow lines of the various objects, thus enabling us to put in very rapidly and with perfect correctness any number of shadows, and avoiding the number of constructional lines otherwise necessary. The student will find no difficulty in obtaining these two points if his perspective has been correctly drawn. The shadows thrown by parallel rays in Fig. 10 also follow the same rules. The student should refer back, and find the shadows of Fig. 10 by means of two similar points.

The shadows of the eaves is easily found; that of P, P 1 will be at $p 1$, the intersection of lines from S and V through P and P 1; $p 2$ is the shadow of point p . RR throws its shadow in the direction Rr from the point V. This shadow continues to the right; the portion of the shadow of G R which is not cast against the roof plane is outside the drawing and against the wall plane. The eaves z cast a shadow in the direction zy from the point V. ARTHUR VIE-PARMINTER.

THE ELECTRIC LIGHTING OF GLASGOW.

IN February next the municipal authorities of Glasgow will enter practically upon the work of supplying electricity to the public for lighting purposes, and it is proposed to light, almost simultaneously, some of the thoroughfares with the new illuminant. At present the scheme is restricted to the central district of the city—from Glasgow-cross in the east to a short distance beyond Charing-cross in the west, and from the Broomielaw in the south to Sauchiehall-street in the north. The corporation have acquired, as a site for a generating station, a square piece of ground at the corner of Waterloo-street and Mains-street, at a corner of about £9,000. On this they have erected, at an additional outlay of nearly £12,000, a structure of three stories, with a frontage of 90ft. to Waterloo-street and 40ft. to Mains-street. The main walls are of stone, the division walls are of brick, and the floors of concrete on iron girders, while iron is employed for the support of the roofs. From the east end of this building a two-story wing goes back a length of about 50ft. at right angles. In its basement floor are five steel tubular boilers of

marine type, and on the floor above there are the storage batteries, of which there are two tiers of 57 cells each. The smoke from the furnaces is carried off by a circular brick stalk 14ft. in height. It is intended to utilise the remaining portion of the site for additional boiler-sheds as the scheme expands. Of the main building, the two upper floors are reserved for offices, the storage of materials, and various minor purposes. The working plant is erected in the basement floor, and will be sufficient to supply 12,000 incandescent lamps of eight candle-power for shop and domestic purposes. The Corporation have adopted the low-tension direct current. The total sum expended on the present installation will amount to about £60,000. It is calculated that the annual outlay for the electric light in the streets operated upon will exceed the annual cost of the gas light by about £500. Professor A. B. W. Kennedy, London, was entrusted by the Corporation with the planning of the whole installation, and the execution of the plans have been superintended by Mr. William Arnot, whom the Corporation appointed as their electrical engineer. Mr. John Porter, Janefield Works, erected the building in Waterloo-street; Messrs. Latimer, Clark, Muirhead, and Co., London, supply the engines, dynamos, pipes, &c. (Messrs. Willans and Robinson, London, constructing the engines as a sub-contract); Messrs. Blakey and Emmott, Halifax, furnish the switchboard; and the accumulators come from the Crompton-Howell Electrical Storage Company.

TOWERS AND STEEPLES.

A LECTURE upon towers and steeples was given at the London Institution on Monday evening by Mr. Arnold B. Mitchell, A.R.I.B.A., of Birmingham, who illustrated his address by a number of lantern photographs taken expressly for the occasion of the various buildings mentioned. The lecturer began by exhibiting a ground-plan of Canterbury Cathedral, pointing out the difference between the two western towers dominating the principal approach to the structure and the grand central tower which was the glory of the fabric. He showed what great difficulties had to be overcome in erecting such an enormous mass of masonry over the open arches upon which, owing to the intersection of the nave and transepts, it was necessary it should be built—difficulties which would account for the fall of some of these towers, for

experienced in consequence of the fouling of the trough from defective formation, and the failure of the flush tank.

The tank here illustrated has neither air-holes nor small pipes, which, as was proved by the

Sheffield Corporation trials, wherever present, choke up and stop the action. It is self-trapping, and untraps at the end of every flush, will work equally well with clean or dirty water, and when used with waste water for flushing drains requires no grease trap. The action is as follows:—There is placed below the tank a tumbler or tipping bucket, into which the long leg of siphon dips, reaching nearly to the bottom. When the water in the cistern rises to the bend of the siphon, it runs down the long leg into the tumbler, thus trapping the siphon and confining the air contained in it. As a consequence, the water in the cistern rises above the bend of the siphon in about the same proportion as in the tumbler. When the tank is filled, the tumbler also is filled to its tipping point, and it discharges its contents, unsealing the siphon, which is instantaneously charged by the head of water in the cistern. The tumbler remains tipped until the finish of flush, when the air passes up into the siphon, effectually unisiphoning it, thus dispensing with the usual leak-off holes or small siphons.

The Sheffield trials proved that this tank could not be put out of order without actual destruction.

The trough is egg-shaped, and has a straight back and front, which gives the flush the greatest scouring power. The rear is set well back from the seat to escape fouling. As a

the devices it had been necessary to invent to keep others intact after they had been finished, and for the fact that the central tower of Westminster Abbey had never been finished. The latter Abbey had the highest roof of any ecclesiastical edifice in England, and its architects found that it would be unsafe to continue the erection over the choir of the central tower, which it would have been necessary to carry up to a great height. Mr. Mitchell traced the gradual growth of the tower from Saxon times, and showed how it became more and more stately and beautiful during the Norman period, and on through the 12th and 13th centuries, until the spire was gradually evolved from the low pyramidal roof which formed the top of the tower. He explained how the steeple went on growing in beauty and grandeur of design through the 14th into the 15th century, when, for some inexplicable reason, the spire was altogether abandoned; but to compensate for the loss, the upper part of the tower was made very ornate, a peculiarity of the Perpendicular style. As an illustration, he showed a photograph of the tower of Magdalene, Cambridge, a most beautiful example, with a wondrous sky-line.

MERRILL'S PATENT FLUSH TANK AND TROUGH CLOSET.

THESE have been designed with the object of providing a thoroughly reliable automatic flushing closet, without the drawbacks hitherto

result of this method of construction, a considerable depth of water is retained in the trough, and the flush rises steadily to the top of trough, as shown by the dotted lines on section, effectually scouring it. They are manufactured by the Water Carriage Engineering Co., Limited, Sheffield.

The friends of the Mayor of Sheffield, Alderman Batty Langley—whose name will recall a past race of architects—received from him and the Mayoress a Christmas card which is the result of a competition amongst some of the students at the Sheffield School of Art for prizes offered by him for the best designs. That selected as being the best is the work of Miss A. Kershaw, who is the holder of a £20 scholarship from the Art Department at South Kensington.

Plans for a proposed new mechanics' institute and technical school at Ripon have been prepared by Mr. George Styant, architect, St. Helen's Chambers, York, and consulting surveyor of the city of York. The site is in Finkle-street, adjoining the old market-place. The front of the building will be of Leeds pressed bricks, with stone dressings. On the left of the entrance is the library and bank-room, 27ft. by 16ft. There is to be schoolroom 50ft. by 30ft., and also a cookery-class kitchen and work-room, each 25ft. by 20ft., in the yard. On the first floor are the reading-room, 29ft. by 24ft.; committee-room, 16ft. by 18ft.; billiard-room (two tables), 30ft. by 22ft.; and two committee-rooms. The second floor provides bedrooms, and the basement caretaker's rooms.

RESIDENTIAL FLATS, MORPETH-TERRACE, S.W.—NORTH WALES TRAINING COLLEGE, BANGOR.—SALISBURY CATHEDRAL SPIRE, FROM THE BISHOP'S GARDEN.—"BUILDING NEWS" DESIGNING CLUB: DESIGNS FOR LOCAL BOARD OFFICES FOR A VILLAGE.—ST. PHILIP'S CHURCH, STEPNEY.

Our Illustrations.

RESIDENTIAL FLATS, MORPETH TERRACE, S.W.

MR. GEO. BAINES, of 4, Great Winchester-street, E.C., is the architect of these flats, but no further particulars have reached us.

NORTH WALES TRAINING COLLEGE, BANGOR.

IN December of last year the North Wales Training College, which has, since its establishment half a century ago, been located at Carnarvon, was partially destroyed by fire, and the Committee of Management, which includes the Bishops of Bangor and St. Asaph, then took into consideration the desirability of not only rebuilding the college, but of its removal to Bangor, which city has, since its selection as the seat of the University College of North Wales, been regarded as the natural educational centre of the four northern counties of the Principality. At a meeting held at St. Asaph early in the present year it was decided to erect new buildings at Bangor. With this object in view, the committee invited four architects to submit plans in competition. Out of these two designs were referred to a sub-committee to examine (with the aid of professional advice) and report upon. Acting upon the recommendation of this sub-committee, the plans submitted by Mr. Robert Grierson, architect, Bangor, were unanimously adopted by the Committee of Management. Tenders for the work were invited by public advertisement, to which eleven firms of builders responded, and at a meeting held last week the tender of Messrs. Parnell and Son, Rugby, amounting to £3,417, was accepted. This contract does not include fittings and furniture, which, together with boundary walls, will probably amount to a further sum of £2,000. The site selected for the new buildings, and which has been generously given by Lord Penrhyn, immediately overlooks High-street, and the new buildings will form a prominent architectural feature in the general view of the city, as it is approached from the railway station. The principal entrance will be from a terrace, which will crown the brow of the hill which forms the southern side of High-street at this point, and along which the buildings will extend upwards of 200ft. The walling will be of local blue stone, with Cefn stone dressings. It is expected that the college buildings will be completed in time for the students and staff to enter into occupation between terms early in January, 1894. Great credit is due to the Rev. J. Fairchild, the Principal of the college, for his exertions in collecting subscriptions towards the new buildings, and in generally placing before the public the value of such an institution in North Wales.

SARUM SPIRE FROM THE BISHOP'S GARDEN.

TO-DAY we give a pencil sketch of the "Silent finger" of Salisbury Cathedral, which is almost exactly of the same height as the spire of Antwerp Cathedral, of which we gave a view last week. The last mentioned is much later in date and very different in conception and design, though both are marked by extreme delicacy and refinement. These are essentially the characteristics of the spire at Salisbury, which, besides being the loftiest in England, is perhaps the most beautifully proportioned spire in the world. It dates from A.D. 1331. Norwich spire is 313ft. high, and Chichester is 271ft. to the finial; but Salisbury measures 400ft. above the pavement, or 30ft. above the top of St. Paul's. Strasburg, the highest in the world, is 463ft. high, and the flèche at Amiens measures 422ft.; while Antwerp is 404ft. high. The drawing which we illustrate is a delicate pencil study by Mr. Charles Spooner.

"BUILDING NEWS" DESIGNING CLUB: LOCAL BOARD OFFICES FOR A VILLAGE.

(See description on p. 908.)

ST. PHILIP'S CHURCH, STEPNEY.

THIS double-page illustration finishes our series of detail and other drawings representing this church, which has appeared in the BUILDING NEWS during the past two months. The sheet shows the bays of the choir and apse, with a half-plan of the sanctuary, whereon the dotted lines indicate the planning and contours of the groining. Mr. Arthur Cawston, A.R.I.B.A., is the architect.

COMPETITIONS.

MULREADY PRIZE.—The council of the Society of Arts offer, under the terms of the Mulready Trust, a gold medal, or a prize of £20, for competition amongst students of the schools of art, at the annual National Competition held in 1893. The prize is offered to the student who obtains the highest awards in the following subjects: (a) A finished drawing of imperial size from the nude living model; (b) a set of time studies from the nude living model (mounted on imperial size mounts); (c) a set of studies of hands and feet from the living model (mounted on imperial size mounts); (d) drawing from the life, done at the examination on May 11, 1893. No student will be eligible for the award who does not pass in the examination (d) in drawing from the life, and who does not obtain an award for (a) the finished drawing of imperial size from the nude living model. The other two subjects are optional. The works must be those of the previous school year. The drawings are to be submitted, with other school works, in the usual manner to the Department of Science and Art, in April, 1893. Each competing drawing must be marked "In competition for the Mulready Prize," in addition to being labelled according to the regulations of the Department of Science and Art.

CHIPS.

The London County Council have deposited in the Private Bill Office a Bill for the removal of 65 obstructions to traffic in the shape of gates and bars in different parts of the metropolis.

The South Kensington Museum has recently obtained by purchase the Venetian marbles acquired by the late Mr. Cavendish Bentinck. These have been divided between the London, Edinburgh, and Dublin Museums—the last two having contributed to the purchase by grants from their respective funds. Another addition to the architectural collection is the plaster cast of the doorway of the Cathedral of Aix, in the south of France.

A statue of the Queen in a sitting position was erected last week opposite the Horse Guards, in the vacant space where Carrington House once stood, next to the Chapel Royal. The statue is only temporarily placed there, as it is to be sent to Hong-kong as a Jubilee monument of Her Majesty. It has been executed by Signor Raggi.

The School Board for Carlisle have instructed Mr. T. Taylor Scott, of that city, to prepare plans for a school, in two departments, to be built in Ashley-street.

A workmen's supper to commemorate the successful raising of the topmost stone of the new church, now in course of erection at Budleigh Salterton, took place at the Rolle Hotel, in that town, on Wednesday week, and was attended by some 40 of the men engaged on the works, under Messrs. Luscombe and Sons, of Exeter, the contractors.

THE DUBROT BRICK AND TILE IRON FRAME.

THIS is a new invention for saving time and breakages in the transport of bricks and tiles which has just been patented by Mr. Dubrot. It is an iron frame like the annexed

figure, holds many bricks and tiles, and allows them to be passed very rapidly if several removals are required. Among its advantages are the following:—(a) It protects the corners of the bricks and tiles from being chipped. (b) It is

quickly fastened and unfastened. (c) It closes into a very small compass for storage. (d) It is easily handled. (e) May be had in any size. The patentee is Mr. Vautier, 29, Halsey-street, London, S.W.

The old and well-known firm of Messrs. Measures Bros. and Co., of 57, Southwark-street, was registered on the 19th inst. as a limited company under the title of "Measures Bros., Limited." We may successfully predict a well-deserved continuance for the new company of the confidence and success the old firm has so long and so justly enjoyed.

At Rushall, near Tunbridge Wells, a public inquiry was held on Friday by Major-General C. Phipps Carey, C.E., one of the inspectors of the Local Government Board, respecting the application of the Rushall rural sanitary authority for sanction to borrow £800 for works of private street improvement, and £700 for sewerage and surface water drainage for Speldhurst. Mr. W. Oakley, surveyor to the authority, explained the plans and sections.

Mr. John Hutchinson, R.S.A., has just completed in the clay the statue of the Regent Moray, which is to adorn one of the niches in front of the Scottish National Portrait Gallery, Queen-street, Edinburgh. The figure is 6ft. 6in. in height. The Good Regent, attired in doublet and hose, wears on his head a soft velvet cap. His right hand grasps a State paper, while his left is at his waist-belt. The head, studied from the Holyrood portrait, shows the Regent in the flower of manhood, with moustache and pointed beard. The figure, which will be carved in red stone, is the gift of the Earl of Moray.

WAYSIDE NOTES.

NO further information is forthcoming with regard to the proposed competition for a London board school. Presumably, the Board are preparing a set of conditions for architects. The action of the Board has been freely condemned, and one certainly feels that the chief idea of the competition from the point of view of the promoters is the gaining of new ideas at a small outlay for premiums. In which case it will be as well if the premiums proposed are of liberal amounts, and at least as much as those suggested by General Moberley, viz., £150, £100, and £50. I hope that the School Board will soon issue particulars for this competition, as its course and result will be interesting to watch.

An excellent thing will be the proposed Workman's Exhibition, to be held at the Agricultural Hall in June and July next year. Anything that will encourage workmen to take an interest in their work is good. An exhibition of the nature proposed should not fail to do some little to forward this end. I trust that the building trades will be largely represented.

In writing of the County Council as concerned with the question of open spaces in London, I was not aware of the extent and scope of the Bill that the Council has deposited in the Private Bill office of the House of Commons. This measure is devoted solely to the question of open spaces, and is divided into eight parts. In Part II. it is proposed to vest absolutely in the Council the fee simple of Hackney Marshes, to which end it is in contemplation to compensate commoners and others possessing beneficial rights in these marshes, at an estimated cost of £75,000. In Part III. the Council propose to acquire the management of, and to maintain, Lincoln's Inn-fields. Part IV. is of an eminently progressive character. It proposes to manage and maintain the Albert Palace for the use and recreation of the people. In Part V. the architect becomes interested, dealing, as this section does, with a proposal to acquire, for the purposes of preserving "as an object of interest," the ancient York Water-gate, the familiar object at the bottom of Buckingham-street, Strand. Power also is sought to acquire some vacant ground adjoining—said to have been formerly part of the terrace walk leading to the gate—at a cost of £1,000. In Part VI. powers are sought to enable the Council to acquire so much of Hilly Fields, Brockley, as will secure not less than 41 acres of land as an open space for public recreation. The first part of the Bill and the remaining sections deal with preliminary matters of form, the making of an additional entrance to Brockwell Park at a cost of £500, and various clauses necessary to carry out the powers mentioned.

Hackney Marshes are to me a memory of gloomy, fog-laden levels, most remarkable as being a free northern outlet for the smoke of Stratford factories; but there are doubtless some clear, sunny days even in this generally cheerless suburb of London. They may, therefore, prove worth acquisition, although the sum of £75,000 seems vastly too much to expend on so unlovely a spot. As to the York Water Gate, it is to be hoped that no ill-advised scheme of restoration is in the mind of the Council. Some time has elapsed since I last passed this pleasing old relic; but it is now, doubtless, as it ever was, sturdy in appearance and sound in condition. Once there was talk about the condition of the keystone of the central arch, but this was probably looked to long ago. All the Council will need to do will be to repair and remedy any signs of structural dilapidation. There is yet a lot of wear in this chubby piece of Renaissance architecture.

Readers may have noticed an amusing *Globe* "turnover" a few evenings before Christmas, entitled "On Building a House." I should think that a more complete heading would have had, further:—"By One who never Built a House, but Writes from his Imagination." Nevertheless, there was much to tickle the architect's fancy in the article. As to the question of architect, "shall it be the well-known Mr. Oriol, of Mediæval propensities, or Sir Inigo Gargoyl, whose red-brick and timber constructions recall the 'times of Great Elizabeth,' or 'days of good Queen Anna'?" And further, "as to the architect, one would be quite as safe with such and such a famous person, provided he

would condescend to do his best; but is not he almost too grand? When he built a house for poor X. Y. Z.'s, he went down only once for half an hour to look at it. There is his favourite pupil, Mr. Octagon, to be sure, just setting up for himself, but it seems rather rash to become the subject of his maiden effort; but then, again, he would take such pains." In the course of the progress of the works, "if you are domiciled close at hand you bring over all the friends who will sacrifice themselves, and delight to pioneer them over rickety planks and through swamps of mud, and induce them to mount a tottering ladder to obtain a clear idea of the exact elevation of the kitchen chimney." In questions of taste, "the architect is serenely complacent. You offer a timid suggestion, which you flatter yourself really is well thought out. He is 'afraid he doesn't see it,' and smiles leniently, but with a covert contempt." After all, the troubles a housebuilder goes through, we are relieved to hear that you "end by becoming very fond of your house, in spite of all its faults and shortcomings."

Harlow Church, Essex, to which I referred last week as about to be rebuilt so far as concerns the nave and tower, is, I suppose, one of those typical churches of the North-west Essex district with a massive square tower surmounted by a sharp spike of a spire rising abruptly from the square parapets, with a base much smaller than the top of the tower, the full blunt square forming a quaint and pleasing contrast to the spiny sharpness of the spire. On Friday, having to journey to Cambridge, I passed Harlow, but did not awaken to the fact soon enough to notice the church (if visible), and when I returned in the evening it was dark. By the way, what a charming old place is Newport, close by! Its curious old whitewashed cottages, with thatched and tiled roofs and elaborate cut-brick chimneys, are well seen from the railway. One house is, I believe, reputed to have been occupied by Nell Gwynne.

In passing through Oxford on my way to Shropshire the other day, I noticed the scaffolding around St. Mary's tower. When Mr. Jackson has completed the work of restoring the tower, and the scaffolding can be cleared away again, the general Oxford skyline will be improved.

Wren's Westminster towers have again come forward. I am inclined to agree generally with "C. F. M." The absurd mania—now, I trust, dying out—for restoring back to certain dates, is certainly falsifying history to no insignificant extent. There is just one other side, however, on the question of the conduct of Wren in putting on quasi-Gothic towers to the old 15th century stumps. As a whole front the effect is doubtless displeasing to most architects. It is quite likely that Sir Christopher thought he had accomplished some very excellent Gothic work indeed when he had added these towers; but we now see there is not an atom of Gothic spirit in this design. Completing a tower is not like adding an aisle. If unfinished towers are never to be completed, we should have been without some of the finest Continental examples, which, begun in the Middle Ages, have, comparatively speaking, been only recently completed.

Your article and "Clerk of Works' " letter open a subject of discussion always of interest to architects. There is room for considerable individuality in the matter of a choice of scale; but as workmen and foremen get accustomed to certain scales, it would seem best that there should be some understood, if unwritten, agreement among architects on this point. One-eighth, one-half, and full-size are the most useful for ordinary work. From the builders' point of view a quarter-inch to the foot is a desirable scale for the general plans; but in a busy architect's office one-eighth inch to the foot is the only practical scale. Certain works may demand a larger scale, both for general plans and details. A small work requiring special attention will necessitate quarter-inch and one-inch respectively. Fads in this way should be avoided. We have had three eighths recommended; but then, if I remember rightly, the gentleman who so advised us also suggested the preparation of the details before the general plans. Certainly the details should be prepared in the head at an early stage of proceedings; but, as made, this was one of the most curious recommendations ever put before architects. GOTH.

OBITUARY.

We regret to announce the decease of Mr. John Gibson, F.S.A., F.R.I.B.A., which occurred early on Friday morning at his residence in Great Queen-street, Westminster. Mr. Gibson, who was in his seventy-sixth year, had been in failing health for some time, and death was caused directly by severe bronchitis and pleurisy. In 1836, when Sir Charles Barry was selected as architect for the new Houses of Parliament, Mr. John Gibson was his only pupil, having entered Barry's office in the previous year, and he accompanied his employer to exhibit the plans and the model to King William IV. and Queen Adelaide. After serving a three years' term of pupilage, Gibson remained with him for six years, and assisted him in preparing the details for the Houses of Parliament, as well as in the designs for University College at Oxford, Trentham Hall, Harewood House, near Leeds; Duncombe Park, and the Board of Trade Buildings, Whitehall. Beginning practice in 1844, Mr. Gibson entered at once on a successful career. Among his chief works were Boddwyddan Church, St. Asaph, erected in 1860 for the Dowager Lady Willoughby de Broke; the National Bank of Scotland at Glasgow; Imperial Office, Threadneedle-street; Romanesque Chapel in Broad-street, Bloomsbury; the mansions of Compton Verney, Wroxton Abbey, Charlecote Park, and Guy's Cliffe, all in Warwickshire; and many large houses in Lancashire. His chief work has been as architect to the National Provincial Banking Company, for whom he built their head office at the corner of Threadneedle-street and Bishopsgate, and most of its branch buildings. He also designed Child's Bank in Fleet-street, the S.P.C.K. premises in Northumberland-avenue (the first building erected in that thoroughfare), the Stock Exchange at Glasgow, and Todmorden Town Hall. Most of his works are of a Classic or Italian Renaissance type, and are characterised by a careful study of proportions and great refinement in detail. Mr. Gibson joined the Royal Institute of British Architects in 1849 as an Associate, became a Fellow in 1853, successively served as a Member of Council and Vice-President, and in 1890 was the recipient of the Royal Gold Medal. Mr. Gibson was one of the eight architects who were requested to send in designs for the New Law Courts; but, after full consideration, he declined on the ground of insufficient space being offered for the accommodation required. We gave a portrait of Mr. Gibson in the BUILDING NEWS for July 18, 1890.

Mr. W. T. Roden, the portrait painter and one of the founders of the old Birmingham Art Gallery and of the Royal Society of British Artists, which has its headquarters at Birmingham, died in that city on Christmas Day, at the advanced age of seventy-five.

Mr. James Greenslade, builder, of Stroud, a member of the local board of health, was one of a party who were shooting rabbits on Monday on a farm at Haresfield, near Stroud. They were about to discontinue their sport at dusk when one of the party threw a dead rabbit over a hedge with the intention that the deceased should catch it. The rabbit lodged on the top of a hedge, and Mr. Greenslade was trying to reach it with the stock of his gun when a twig pulled the trigger, and the contents of one barrel entered his side. He died the following day in Stroud Hospital.

Messrs. Reed, Blight, and Co., Limited, contractors, have removed their head offices from Sutton Harbour, Plymouth, to Albany Buildings, 47, Victoria-street, Westminster, S.W., where all communications should be now addressed.

John McCarron, mason, Duncan-street, Glasgow, has been awarded £35 and legal expenses by Sheriff Erskine Murray, in an action against David Short and Son, builders, 68, Bath-street, Glasgow, for injuries sustained by a fall of the jib of a crane at Lambhill on Aug. 4 last.

The tower of Kingston Church, near Taunton, one of the most beautiful in the county of Somerset, has just been restored. The work was intrusted to Messrs. Vickery and Poole, of Milverton, the architect being Mr. J. Houghton Spencer, of Taunton. The rough-cast which covered the upper portion has been removed. The whole of the stonework has been pointed, and the parapet tracery has been strengthened by removing the iron stanchions and replacing them with copper ones. Lightning conductors have been placed on the pinnacles, and the weathercock has been reset and regilt.

THEATRES.—XV.

By ERNEST A. E. WOODROW, A.R.I.B.A.

THERE are plans of the approaches of two old Parisian theatres, which I reproduce from Mr. Gosset's work, and which are of sufficient interest to be included in the series of drawings of grand vestibule and staircase which have been published in the two preceding chapters. Fig. 1 is the opera of the Palais Royal, burnt down in 1781, which was built by M. Moreau, the architect, in 1764. Fig. 2 is the vestibule Théâtre Français, as it was in 1789, bordered in the front by the Rue Richelieu, and on the side by Rue Montpensier. M. Louis was the architect. The theatre was built in 1787.

Before concluding my references to the arrangements of the auditorium and approaches of the theatre, I have little left to say. When that little has been said, it is my intention to treat with the stage and its appurtenances in the same manner as I have done the front of the house, and to describe somewhat shortly the broad outlines of the stage machinery, in order that architects may the better comprehend the necessities of some of the provisions demanded in the planning and construction. When dealing with the mode of constructing a theatre, I hope to be able to furnish the readers of the BUILDING NEWS with some working details of one of the latest and most modern play-houses in London, which have been furnished me for that purpose by the courtesy of the manager of the Horseley Company Ironworks. After this digression, I

FIGS. 1 AND 2.

FIG. 4.

must proceed to dispose of the subject immediately in hand in this and the following article.

When the audience has ascended the staircases, to the consideration of which we have devoted the last three chapters, it is for the architect to determine the best level for the corridors in

relation to the tiers, and the best position of the entrance from the corridors into the tiers.

The general plan, as is well known, is to have a corridor round the back of the tiers at the same sweep as the back wall of the circle, as has been seen in the illustrations of the Continental

FIG. 3.

theatres which have been produced in the past three papers, and to have a passage-way passing down each side of the tier. The doors to the back corridor should be on a line with the gangways. In recent plans the doors into the side passage-ways are placed at the end of every row, or a door is made available for two or more rows. This arrangement compels the occupants of the seats in the various tiers to ascend towards the corridors before they descend the staircases—a custom which Mr. Tarver, in a paper read before the Sheffield Society of Architects in 1888, strongly condemned.

The accompanying Fig. No. 3 is an illustration of a side corridor of the dress circle of a theatre, showing the actual dimensions of the rise of each row of seats above a given datum line—in this case the vestibule level. It will be seen that for nine rows of seats there are three doorways into the side corridor in addition to the doorways in the back wall leading to the back corridor. It will also be seen that anyone seated in the front row must rise 11ft. 3in. to the back corridor before descending the same distance to gain the vestibule.

Now, Mr. Tarver, in his lecture, dwelt at some length on this point. "A theatre," said he, "is a building in which part of the audience is sometimes placed below the street level, and—almost invariably—several parts of the audience are placed above the street level, and the question is how are the occupants of these respective parts to reach the same level most rapidly? I say that those who are below it should, on leaving their seats, begin to ascend towards it, and that those who are above it, on leaving their seats, immediately begin to descend towards it. This sounds a very simple proposition, and yet I do not know of any theatre (except the Criterion, which is entirely below ground) where this mode of egress is adhered to throughout all parts of the house.

"On the contrary, the usual custom is as follows:—When the occupants of the upper portions of the house (except those in the back, or worst, and therefore most empty row) wish to get out, they have to ascend up to that same back row, to pass through a door, generally into an inclosed passage, and then they have to begin to descend again. In the gallery, or highest portion of the house, this will mean to the occupants of the front row (which, being the best, will always be fullest) an ascent of about 10ft. up, and then a descent of 10ft. down again, equivalent to 40 unnecessary steps of 6in. rise, as well as a journey of some distance along an inclosed passage. Now when all this double journey has been performed, those who started from the front row are precisely at the same level as when they left their seats, and they have still the remainder of the descent to complete down to the street level."

Mr. Tarver argued that the necessity of the admission of the people to their seats at a high level is caused through the custom of introducing the foyer at the back of the seats. "The ancient Romans, under the Empire, were proverbially luxurious, and yet their amphitheatres do not contain vestibules for the various parts of these buildings. On the contrary, they consisted exclusively of seats to see from, and stairs to get in and out by." The lecturer admitted the desirability of saloons as a resort to relieve the tedium, and in which to take refreshment during the time the curtain is down between the acts, and in his scheme said it would be found that he had not neglected the provision for ample saloons in what he considered the proper place.

There is no doubt that this was the origin of the entrance to the seats from the corridors at a high level in the opera houses; where the tiers consisted of continuous private boxes right round the "circle," these were shallow and with no ascent to speak of up to the corridor. In the dramatic theatre, with several rows of seats in each tier, the circumstances are somewhat different, and the rise from the front row to the back row considerable, as seen in the illustration (Fig. 3).

Another argument which has been used in favour of the low-level exit is, that as smoke ascends to the back of the tier, the audience would be escaping from the rising smoke by descending to the doorway at the bottom of the tier in lieu of ascending to the doorway at the top of the tier.

It is very doubtful if the abolition of corridors would be a step in the direction of improvement to theatre planning; in fact, it would appear to be quite the reverse, for the corridors should be of such construction and dimensions, and so shut off from the auditorium by brick walls and lightly-made fire-resisting doors as to form in themselves harbours of refuge into which the audience could immediately fly should danger arise in the auditorium, and be cut off—at any rate, for a time—from the smoke and flames. Where the stage is effectually divided from the auditorium, and the auditorium from the corridors, and there are good exits and good staircase leading directly into the street, on both sides of the house, from the corridors, there will be but slight chance of a catastrophe, provided the audience behave with reason, and not as wild beasts in a panic; and if the audience know of the means of safety provided for them, they will doubtless not become excited and unmanageable. The corridors of each tier should be large enough to take the whole of the occupants of the tier without crushing; they should be fire-proof in construction, in direct communication with the staircases, and be provided with external windows, from which outside aid could reach the audience in cases of a panic or block. External

balconies or staircases from these windows would be of the greatest service.

In support of this opinion I quote the following: "The lobbies, corridors, and landings should be separated from the auditorium proper . . . by a sound, strong wall of masonry, with the necessary number of openings for the transaction of business, fitted with strong wrought iron doors . . ." the corridors "should be of such a capacity that they could hold on emergency the whole of the persons accommodated in the parts of the theatre opening on them: with such an arrangement as this, an audience would have an almost absolute certainty of safety in case of accident on the stage, as there would be first the metal curtain, which would keep the flames back for a considerable time, next the immediate exit into lobbies and passages, where they could shut the iron doors behind them, and finally the retreat into the open air, which, under such circumstances, could be made at leisure."

The spaces to be allowed in the corridors for persons has been calculated by an authority as follows:—A crowd can be packed so that each person occupies only 1½sq.ft.; this is very close, and in a moving crowd must be looked upon as dangerous; even allowing 1½sq.ft., there is no safety for the women and children. It has been laid down that a number of grown persons placed loosely together—that is, just touching each other, will occupy upwards of 2sq.ft. each, accurately speaking 2½sq.ft. for every ten persons, but this must be taken as below the allowance which should be given for a crowd filling a corridor. Sir Eyre M. Shaw's rule is for every hundred persons in a theatre the passages, stairs, halls, &c., with immediate access from the several parts of the auditorium, should comprise an area of not less than 250sq.ft., and that the wider the passages and doorways are, the more favourable they are for safety. Thus, while a space of 100ft. by 2½ft. would be sufficient, one of 50ft. by 5ft. would be preferable, and one 25ft. by 10ft. infinitely better.

Now Mr. Tarver in the lecture above mentioned gave his opinion (and it is worth considering) that the true safeguard in emptying a theatre was in the abolition of these inclosed passages which give a crowd no chance of expanding, and in the shortening of the staircases from the upper parts of the house. It is true that corridors which do not allow the free circulation of the crowd must be an evil, not as corridors *per se*, but in their insufficient dimensions and inadequate arrangement.

Fig. 4, the plan of the "Nouveau Théâtre de Mayence," shows an excellent arrangement of external corridors, with free circulation for the audience.

Much has been said at one time and another of the desirability of treating theatres and places of public amusement, like steam-boats and the

COTTAGES PRESTON-BROOK & WARRINGTON
FOR SIR GILBERT GREENALL, BART.
T. BEESLEY, ARCHT.

omnibus, and licensing them to contain a fixed number. This provision would be one of great assistance to the architect, as the manner in which buildings are treated is not always fair to the designer—say, for instance, an architect produces plans for an auditorium in which one thousand people are to be seated, and that upon that data he calculates the number and width of his passages, staircases, and exits, in accordance with the rules laid down by the authorities of the locality—it is neither fair nor just that the building should be made to hold, perhaps half as many again, by crowding the seats, passages, and gangways. The evil of this has been seen by the Middlesex County Council Licensing Committee, and at their recent sessions they introduced a new rule which compels the licensee to keep posted up at the doors notices showing clearly for how many persons accommodation is provided in the different portions of the building, according to the Middlesex County Council regulations, and any infringement of this rule, the chairman said, would be looked upon at the next licensing meeting as forming a ground for non-renewal of the license. Where a theatre is a theatre pure and simple, there will be little or no difficulty for the managers to carry this desirable regulation into effect; but where the house is a theatre of varieties or a music-hall, where the audience is a constantly moving one, it will be hard to regulate the numbers in each division of the house during the performance. At one time, when a popular favourite occupies the stage, the house may be crowded, and in half an hour a portion of the audience may have left the building; then, it is to be presumed, the manager would be at liberty to admit a number equal to that which had left; but how he is to regulate the distribution of the number to the different parts of the house, is a difficulty which scarcely comes within my province to try and solve; but this is the difficulty which has doubtless restricted the universal adoption of the rule to license a building to hold a specified number. If the rule could take the form that no more should be admitted at one time than there are seats provided for in the theatre, perhaps the architect would be pro-

tected against the chance of his building being made to contain more people than he provided safe means of escape for.

COTTAGES, PRESTON BROOK.

THESE cottages are now being erected on the estate of Sir Gilbert Greenall, Bart., one pair at Preston Brook and another pair at Walton, near Warrington. Each cottage contains a living room, washhouse, pantry, and coal place, three good-sized bedrooms, and ample cupboard accommodation. The earth closets and dust are 30ft. from the building. The materials, Ravenhead bricks and Ruabon brick dressings (cavity walls); red sandstone for sills, heads, and mullions; internal walls of washhouse and lobby salt-glazed bricks 4ft. high. Roofs, blue Welsh slates. All eaves for walls, gables, and dormers project 12in. over. Pathways paved with blue Ruabon chequered tiles. A special feature is introduced in the gables by using bricks in imitation of wall tiling. These are made by Mr. Edwards, of Ruabon. The contractor for one pair of cottages is Mr. Jos. Houghton, Higher Whitley, Cheshire; the other pair is built by Mr. R. Beckett, of Hartford. Mr. T. Beesley, of Warrington and Earlestown, is the architect.

COTTAGE HOSPITAL, GALASHIELS.

THE cost of this building, when complete, will be about £3,000. Messrs. Robert Hall and Co., builders, of Galashiels, are the contractors, and the architect is Mr. John Wallace, of 32, Alva-street, Edinburgh.

The east window of St. George's Church, Stalybridge, has been filled with stained glass to commemorate the jubilee of the consecration of the church. The principal subjects are the Nativity, Crucifixion, Resurrection, and Ascension of Our Lord. The Four Evangelists occupy the lower portions of lights, and in the tracery openings are sacred symbols. The work has been executed by Mr. William Pape, of Leeds.

Engineering Notes.

ELECTRIC RAILWAYS IN LONDON.—Two Bills have been deposited at the Private Bill Office proposing the construction of new electric underground railways in London. The Clapham Junction and Paddington Railway Bill seeks powers for a subway, four miles one furlong long, from St. John's-hill, Wandsworth-road, to Bishop's-road station on the Great Western Railway. The capital of the company is fixed at £1,050,000. The Edgware-road and Victoria Railway Bill provides for the making of an electric subway, four miles and three furlongs in length, from Edgware-road to Vauxhall Bridge-road at Victoria. The capital of the company in this case is fixed at £1,200,000. The City and South London Railway Company have also deposited a Bill asking for an extension of time for the construction of the subway authorised by their Act of 1890.

NEW RAILWAY BETWEEN BIDSTON AND THE DEE.—The Manchester, Sheffield, and Lincolnshire Railway Company are to extend their system into Birkenhead. The new line through the Hundred of Wirral is to commence at Bidston by a junction with the Hoylake and Deeside Railway at the North Locks, Birkenhead, and to continue on through Upton, Woodchurch, Storeton, Barnston, Leighton, and Newton, then on through Burton as far as the Marsh. It will join the Hawarden line by an embankment. The cost of the scheme will be about £250,000. Mr. Francis Fox, of London, is the engineer. Messrs. Monk and Newell, dock and railway contractors, of Liverpool and Bootle, are the contractors for the construction of the line, and they will begin operations next week.

Another addition has been made by Sir Frederick Burton to the series of works by the Netherlands painters in the National Gallery. It is "La Jeune Musicienne," by Jan Van der Meer, and represents a young woman standing at a harpsichord in a brilliantly-lighted room. The dimensions are 16in. by 20in., and it is hung on a screen in Room X.

COTTAGE HOSPITAL: GALASHIELS: JOHN WALLACE ARCHITECT. EDINBURGH.

Building Intelligence.

ASPATRIA, CUMBERLAND.—Extensive additions and alterations are at present in progress at the buildings of the Agricultural College, Aspatria, from plans prepared by Mr. T. Taylor Scott, F.R.I.B.A., architect, of Carlisle. Two houses occupying a portion of the site have been removed, and one extensive wing—T-shaped—has been erected, the larger portion being three stories high, and consisting of a large new classroom, smoke-room, reading-room, &c. A dining-hall, billiard-room, and private rooms are being built at the opposite end of the site. A large tower has been erected in the centre of the main wing forming a portion of the new reception hall, with stained-glass screens at both ends. In addition to the above, a new front elevation has been formed.

CANTERBURY CATHEDRAL.—The west window in St. Anselm's Chapel has just been filled with stained glass. The subjects are figures of the two Archbishops, Simon of Mepham and Thomas Bradwardine, both of whom are buried in St. Anselm's Chapel, and four medallions filled with scenes from their respective lives.—The work to be paid for by the Beaney bequest is now in progress in the crypt, under the care of Sir Arthur Blomfield, A.R.A., as architect. This work consists in excavating to the original floor level, and paving with stone. Unfortunately, the £1,000 left by Dr. Beaney will not suffice to complete the work, and through agricultural distress the funds of the Dean and Chapter have been so reduced that they will be wholly unable out of them to complete the work.

CHACEWATER.—The church of St. Paul, Chacewater, was reopened on Tuesday, by the Bishop of Truro, after rebuilding. Erected 65 years ago, the church consisted of a parallelogram 90ft. by 53ft. wide, and a small chancel 15ft. wide and only 7ft. deep, whilst a projection of only 18in. in the middle of the north and south walls did duty as transepts. Raised 12ft. above the floor were enormous galleries, crowded with pews, and a plaster ceiling covered the entire area at a height of 32ft. from the floor. The new building consists of nave and chancel, with north and south aisles to both, and the old western tower has been retained until something worthier can be provided. The nave is 62ft. long and 24ft. wide, the total length being 110ft., and the extreme width 53ft. The north and south walls have been lowered from 30ft. to 14ft., the window openings being retained and new granite three-light windows with cusped heads inserted. These walls are connected with the new clerestory walls over the new arcades by a lean-to roof, thus forming north and south aisles. The arcades are of local granite, the shafts of the piers being of Polyphant stone. The roof is an open barrel of the old Cornish type. The chancel is separated from the nave by a low screen of granite and Polyphant stone. The east end is filled by an old east window of the parish church of St. Mary, Truro, given by the rector and vestry of the new Cathedral Church. It is Portland stone, with five lights, and its old stained glass, executed early in the present century by Warrington, has been restored by Messrs. Farniloe, of London. No portion of the old fittings could be reused, except the font, which was designed by the late Mr. J. D. Sedding for the parish church of St. Erth. The seating throughout is new, the nave seating being of red deal, with traceried ends. The chancel seats are of oak. The lectern is of oak, and has been executed by Mr. Harry Hems, of Exeter. The contractor is Mr. W. H. Moyle, of Chacewater, and the architect Mr. Edmund Sedding, of 7, Buckland-terrace, Plymouth.

EDINBURGH.—A new home for the nursing staff of Edinburgh Royal Infirmary was formally opened on Monday. The home is situated on the west side of the main corridor connecting the surgical and medical departments. It is built in the form of a square with a garden in the centre, and is connected with the nurses' dining and reading rooms by a conservatory. Two stories in height, the building is faced with red pressed bricks with yellow stone dressings. The internal accommodation consists of 121 nurses' rooms, a sick-room with six beds, and two separate sick-rooms, 16 bath-rooms, and a large recreation-room. The building was designed by Mr. Sydney Mitchell, architect, of Edinburgh.

MANCHESTER CATHEDRAL.—The reconstruction of the floor of the nave, aisles, chapels, and tower entrance of Manchester Cathedral was begun in June last, and has just been completed. The new floor is laid 6in. lower than the old one. The floor of the main aisles and tower have been paved with Carrara marble in squares of dove and white, laid diagonally, having an ornamental border of rouge Griotte, white, and black marbles. The remaining portions of the floor have been laid with Patteson's mosaic adamant of a red colour, and bands of grey marble are inserted. The work has been carried out by Messrs. J. and H. Patteson, of the Oxford-street Marble Works, Manchester.

NEW YORK.—Bishop Potter laid on Tuesday the corner-stone of the new Episcopal Cathedral of St. John the Divine, the ceremony, which was a most imposing one, being attended by a number of bishops and a great body of clergy. The estimated cost is between one million and two millions sterling. The style is an adaptation of Romanesque details to Middle Pointed outlines, and the plan of the completed structure shows a nave with lofty clerestory and low aisles, apsidal-ended choir with chevet of seven chapels (in which on Sundays services will be performed in seven different languages for the benefit of the mixed population of the city), transepts, and south morning chapel. A lofty spire will mark the crossing, and two others will flank the west front. The architects are Messrs. Heins and La Farge, whose design submitted in competition was illustrated in the *BUILDING NEWS* for April 3, 1891.

ROSEASH, DEVON.—Extensive works of restoration have been carried out at Roseash Church. The nave was restored in 1888-90, and the chancel has now been reopened after reconstruction. The dimensions of the chancel are 21ft. by 17ft., and the work of reconstruction was intrusted to Mr. Clotworthy, of Witheridge. The oak screen has been cleaned and restored by Mr. Clotworthy, who also executed a new oak altar-table, from designs by the architects, Messrs. St. Aubyn and Wadling. On the north side of the church there is a Jacobean screen, dated 1618, which has undergone cleaning.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

THE DUNDEE INSTITUTE OF ARCHITECTURE, SCIENCE, AND ART.—The annual conversazione of this institute was held last (Thursday) evening at the Victoria Art Galleries, when an opportunity was afforded the members and friends of viewing the historical and artistic objects forming this year's exhibition of "Old Dundee." An address was given by the president, Mr. W. Mackison, F.S.A.Scot. The following is the programme for the session:—January 5, A. H. Miller, F.S.A.Scot., Dundee, "Curiosities of Architecture in Dundee"; January 19, D. Cunningham, M.I.C.E., Dundee, "Harbours and the Discharging of Vessels"; February 23, Arch. Macpherson, architect, Edinburgh, "Theories of Architectural Proportion"; March 13, Professor J. E. A. Steggall, M.A., Dundee, "The Influence of Town Life on National Character"; April 20, Frank Young, F.R.S.E., F.C.S., Dundee, "The Influence of Minute Quantities of Impurities on the Properties of Useful Metals."

THE ROYAL SCOTTISH ACADEMY.—The prizes awarded by the Council of the Royal Scottish Academy for studies of the figure in the Life School were presented on Friday in the library of the Academy at Edinburgh. The President of the Academy, Sir George Reid, occupied the chair. The Secretary (Mr. George Hay, R.S.A.) read the report of the Council on the Life School. The prize-takers were:—The Chalmers Bursary, Robert J. Brough; extra prize for painting, A. Coutts Fraser; the Chalmers-Jervise prize for the best drawing from the life, A. Coutts Fraser; for the second best drawing from the life, James T. Murray; MacLaine-Watters medal, Robert J. Brough; the Stuart prize, W. Skeoch Cumming and Robert J. Brough—equal. There being no work of sufficient merit by a student in this year's exhibition, the Keith prize was withheld.

The ratepayers of Lancaster have resolved by a decisive majority to adopt the provisions of the Public Libraries Acts.

Correspondence.

DRAINING AND PLUMBING SPECIFICATION.

To the Editor of the *BUILDING NEWS*.

SIR,—I agree with Mr. Dicksee that waste-pipe should not be carried down into cistern-head; but unless the pipe is so fixed as to shoot the water into the cistern-head, it is very likely, in more ways than one, "to discharge over it." Mr. Dicksee's suggestion with reference to the use of a wide R.W. head, may prevent the waste-pipe from drawing air from up the more or less dirty length of pipe below R.W. head; but will not prevent air (or London fog either if in the neighbourhood), from passing "freely" through these pipes direct into the building.

When the difference between external and internal temperature is very great, the rush of air through an untrapped open 1½in. waste would be very objectionable, and although it would prevent said pipe from becoming "foul," it would not, I imagine, be considered a "perfect success" by the average householder, who would probably object to sink, bath, and lavatory wastes being arranged to act as inlet ventilators. I quite recognise the objections to use of traps in these wastes, owing to liability to stoppage, &c., and the difficulty of clearing same, even when fitted with clearing screw-cap, and was in hopes that in condemning the use of them Mr. B. D. had some other and more preferable way of preventing the inrush of damp air, fog, and, in some cases may be, dust and effluvia.—I am, &c., F. S. I.

VENTILATION.

SIR,—I do not quite see the necessity for all the elaborate statements which are being made in connection with the above subject. Everybody, who has any knowledge of it at all, knows that mechanical or artificial ventilation is, in actual practice, unreliable and unsatisfactory, however feasible or admirable it may appear in theory. Some will stoutly maintain the contrary, and marshal forth a mass of statistics in proof of their assertions; but all the same they cannot in any way alter the facts as they are actually found to exist, and which, as Burns says, "are chieft that wunna ding,"—though I am not quite so sure of my Scotch. Automatic ventilation is all very well in its way, but I have seen as many failures with it where it has been ignorantly and unskillfully applied as with mechanical methods, and I quite agree with your correspondent that the greatest care should be taken in the selection of automatic ventilators, as everything depends upon that, there being so many contrivances before the public now which are only ventilators in name.

The climate of this tight little island of ours is, goodness knows, damp enough already, and any mode of ventilation, and I am aware that such exist, that increases the moisture in the air of a building cannot be too strongly condemned.

How is it that the biggest sinner of all has not been "named" in this discussion—viz., heat as a ventilating agent? The failures of this method of ventilation are, I should say, considerably in excess of either mechanical or automatic; and yet no mention was made of it.

Why should Captain MacIlwaine go out of his way to resurrect the past mistakes of the Sanitary Institute?—even though that body might have made attempts to verify them. The "Kew farce" was not taken seriously by the public, the results being too manifestly absurd; so that no great harm was done, and the Institute has doubtless accepted the warnings it received from the *Times* and other sources, which were severe enough in all conscience, and has been trying its best to retrieve itself, and regain the confidence of the public, so that it is hardly fair to have the blunders of its salad days so needlessly raked up again, to make a Roman holiday for the experts. It surely ought to suffice that the president of the Sanitary Institute, Sir Douglas Galton, who, from his position, ought to know what he is talking about, states that an open pipe cannot be relied upon as a means of ventilation. Of course, we all know that; but there is no satisfying some people. With regard to what constitutes good ventilation, it is all very well for experts to say that 150c.ft. of air per hour is necessary for health, when it is safe to say that in not one building out of a dozen is anything like that quantity provided.

What is wanted is a little more practical work and a little less theoretical talk about these matters.—I am, &c., C. E.

Intercommunication.

QUESTIONS.

[10919].—**Joists.**—An opening in a 14in. brick wall 15ft. wide has to carry a load of 17 tons 5cwt. uniformly distributed. I wish to employ two R.L. joists with a plate riveted on the top, the depth of joists not to exceed 13in. What additional strength is gained by adopting this method? Can the lists published by the various merchants be relied upon as to safe loads, depths, &c.?—INQUIRER.

REPLIES.

[10918].—**Strains in Girders.**—There are several good books on strains on bridge girders and trusses, but I cannot think of any that explain the first principles well. Perhaps the best are Stoney's "Strains in Girders and Similar Structures," Cargill's "Strains in Bridges and Roofs," Adams' "Strains in Ironwork" (a cheap elementary book), Humber's "Bridge and Roof Formulae" (a good little book for the office, but of not much use to a man who wishes to grasp the principles of the subject), and Clark's "Graphic Statics." There is no doubt if a few elementary principles were thoroughly mastered, you would find that you could make great progress by books alone.—J. R. PORTER, A.M.I.C.E.

Legal.

CONSTRUCTION OF COVENANTS.

A FREEHOLD house in a square in Newcastle was sold, and at the time of the sale there was an open space in the centre of the square used as a garden. With the obvious purpose of preserving that square as it then was, the purchasers took a covenant in the words following:—"And it is hereby agreed and declared by and between the parties hereto that the garden or open space coloured round with green upon the plan is for ever hereafter to be kept open and unbuilt upon." This appears to have been thought sufficient, and the covenant did not go on to specify that the space should be kept as a garden or square, nor that no building should take place below the surface. In the recent case of "Graham v. the Corporation of Newcastle-on-Tyne" (*Times*, December 11), this covenant came before the Court of Appeal for construction, the defendants having built under the surface of this open space a urinal having an exit and entrance fronting the dwelling-houses round the square. The plaintiff had applied to Mr. Justice Kekewich for an injunction to stop the work; but, as was here noted at the time, he refused, and hence the case was taken to the Court of Appeal.

The Lords Justices have now confirmed their decision, and have construed the covenant with a strictness and a narrow technicality worthy of the strictest times of the old common law courts. They have held that it is no breach of such a covenant to build below the ground in question. All the covenant provides for is that the space shall remain "open and unbuilt upon." Buildings underneath are not within its scope. There was nothing specified in the covenant as to its being kept as an open square in the centre of dwelling-houses. All the plaintiffs could claim was free access of light and air by the ground remaining "open and unbuilt upon." It was argued for the plaintiff that the defendants had no right to interfere with the surface by any buildings, and as the defendants had done this by building air-holes and ventilators, they had broken the covenant. The Court of Appeal, however, would not have it so, and thus, instead of a square or garden "open and unbuilt upon" for ever, the dwelling-houses around look out upon the top of an underground urinal, with glass lights and air-holes, and with an exit in front of their street doors!—all of which shows how carefully such covenants should always be drawn.

FRED. WETHERFIELD, Solicitor.

1, Gresham Buildings, Guildhall, E.C.

NOTE.—All questions for reply in this column must be headed "BUILDING NEWS," and must reach my offices, as above, by Tuesday morning to insure answer same week.

The Aberdeen Infirmary and Asylum Corporation agreed on Tuesday to reconstruct the Royal Lunatic Asylum, and erect a hospital in connection with the institution, at an estimated cost of £50,000.

LEGAL INTELLIGENCE.

RE J. HICKMAN.—James Hickman, builder, of Chester-road, Stretford, and of Heswall, Cheshire, appeared for his public examination at the Salford Bankruptcy Court on Monday. The liabilities amount to £5,440 11s. 7d., and there are no assets. The bankrupt stated that he had been in business from 1862 to the end of 1890, but always without capital, and during the past two years he had been superintending the erection of houses on land he had mortgaged, the mortgagee allowing him £2 a week for his services. His stock-in-trade was sold under an execution in 1890. The furniture he was now using was hired by his wife, who had property of her own. In or about 1862 he was made a bankrupt in the Liverpool Court. His liabilities were about £2,000, and he was not aware that any dividend was paid. His further examination was adjourned.

"OWNERS" UNDER THE BUILDING ACT.—At Clerkenwell Police-court on Tuesday a decision of interest to agents of house property in London was given by Mr. Horace Smith. Mr. Edward Stimpson, house agent and auctioneer, New Kent-road, had been summoned by the sanitary inspector of Clerkenwell for penalties for not obeying an order to have the drains upon premises at 8, Providence-row, repaired according to notice served. Mr. Bodkin, for the defence, had submitted that Stimpson, being only agent for the collection of the rent of the premises, and without any authority to expend money, could not be ordered to do the work required, for the reason that he had disclosed immediately on receipt of the summons the name and address of the actual owner; and further that he was not such an agent as was contemplated by the section defining "owner." Mr. Bodkin now added that the owner had since come forward and directed the work which was now being completed. Mr. Horace Smith said that the agent must be taken as responsible for the owner. He fined Mr. Stimpson 20s. and costs. He consented to state a case for the High Court, but ordered the fine to stand.

EXAGGERATION NOT A FALSE PRETENCE.—Arthur Coles, builder, of St. George's-place and Park-lane, Kensington-gore, was summoned to the Westminster Police-court last week by William Gidney, an apprentice, charging that the sum of £32 10s. was obtained as a premium by false and fraudulent pretences, and with intent to cheat and defraud. The representatives of the boy communicated with Mr. Coles through an advertisement. It was ultimately arranged and settled by indenture and the payment of £32 10s. premium, that the boy was to be taught the trade of a carpenter and joiner. Mr. Coles was alleged to have represented that he employed a certain number of men, that he had important works on hand, and facilities for teaching the trade, all of which statements were now traversed, and asserted to be false. Moreover, it was said that the defendant was in pecuniary difficulties at the time he took the premium, as evidenced by the fact that a County-court judgment for over £30 had been obtained against him. For the defence it was urged that defendant had done nothing which could bring him within the criminal law. The boy had had instruction in his trade. Mr. De Rutzen decided that the defendant's representations when taking the apprentice only amounted to exaggeration. He must dismiss the summons.

IN RE D. PRICE, NANTYMOEL.—A meeting of the creditors of Daniel Price, 12, Osborne-terrace, Nantymoel, builder, was held at Cardiff last week. The debtor's gross liabilities were returned at £4,695 16s. 7d., of which £2,867 4s. 6d. was expected to rank for dividend. The deficiency amounted to £2,867 4s. 6d. The debtor attributed his failure to loss on a contract for the erection of 34 cottages at Tynewydd. In 1893 he commenced business on his own account as a speculative builder and contractor with a capital of about £50, and erected about 114 cottages, all of which he sold, except 32. In June, 1891, he entered into a contract to erect 34 cottages for the Tynewydd Building Club at £144 per house. Eleven of these he finished, and was paid for; seven he got under cover, but the work was delayed, and on August, 1892, the contract was cancelled and all the plant and material seized. The contract was re-let to the debtor's foreman at £32 per house more. The debtor estimated that upon this contract he lost £1,008—£56 per house.

THE LIBERATOR BUILDING SOCIETY.—The charges against J. W. Hobbs, builder, and H. G. Wright, solicitor, of forgery and illegal appropriation of money in connection with the Liberator Society were further heard on Friday before Mr. Vaughan at Bow-street. Evidence was given with respect to the bills alleged to have been forged and uttered by the accused, and also in reference to goods supplied to Hobbs for the Norbury Farm, Streatham, by the firm of Hobbs and Co., Limited, and to the manner in which the defendant's indebtedness on this score—to the amount of £2,279—had been wiped out by transference to certain accounts in the company's books. Witnesses were called to support a charge

against Wright of illegally appropriating to his own use a cheque for £2,500. The case was remanded till January 12, and the accused were again liberated on bail, which was, however, increased to £3,000 for each.

THE QUESTION OF FIXTURES.—The hearing of the case of "Chaplin v. Chapman," adjourned from last Court day, was resumed before Judge Hooper at Loughborough County-court on the 22nd inst. The plaintiff was Fanny Chaplin, wife of Marmaduke Kay Chaplin, builder, Etwell, Derby, and the defendant Joseph Chapman, timber merchant, of Grimsby, and the plaintiff claimed £50 for machinery detained on premises in Regent-street, Loughborough, and defendant entered a counter-claim for £28 10s. for the use and occupation by plaintiff of a saw-mill in Regent-street. The action arose out of the bankruptcy of W. Needham, who for some years carried on business in the saw-mill and premises in Regent-street, Loughborough. On three occasions he mortgaged his property, and the defendant purchased interest under the first mortgage. The plaintiff purchased part of the estate from the trustee in bankruptcy, and thus both parties became connected, and the question at issue was whether certain machinery, valued at £50, on the premises was or was not fixed on the premises. If it was fixed it passed under the mortgage; if not, the plaintiff was entitled to it under her purchase from the trustee in bankruptcy. At the last hearing evidence was called on behalf of the plaintiff to prove that they were not fixtures, and a denial was made that the plaintiff had used or occupied the saw-mill. Mr. Toller, on behalf of the defendant, said the evidence on behalf of the plaintiff had been designed to prove that the machinery was only temporarily fixed to pieces of wood to add to the stability; but he contended, upon cases which he quoted, that if they were so fixed, and added to the value of the machinery or premises, they passed under the mortgage, and this was the case he submitted here. Mr. Vachell replied for plaintiff, contending that none of the machines were attached, that they were merely goods and chattels, and not fixtures. His Honour gave judgment for defendant on the claim and for 40s. for mean profits on the counter-claim. He allowed costs on the highest scale.

RE WILLIAM COLES.—The debtor, an ex-mayor of Winchester, builder, Kingsgate-street, Winchester, filed his own petition, and the public examination took place on the 22nd inst. He filed his liabilities at £2,086 7s. 5d., assets £400 7s. 11d., and deficiency £1,685 19s. 6d. He attributed his position to loss on contracts, failing health, and competition, and depression in trade. He was examined by the Official Receiver mainly as to an arrangement with his creditors in 1893, under which they were to receive 12s. 6d. in the pound, and it was elicited that only some of them were paid.—The debtor was allowed to pass.

"GRINDING MONEY."—Three carpenters who had worked at Knightsbridge for Messrs. Higgs and Hill, builders and contractors, of Lambeth, sued the firm at the Westminster Police-court on the 22nd inst. under the Masters and Servants Act for an hour's wages—9½d., "grinding money," which they alleged was due to them under the agreed rules of employer and employed governing the building trade.—Mr. Mabon, solicitor, who appeared for the defendants, said that it was a bona fide dispute, and it all turned on the construction of one rule, which was most ambiguous in its terms. The workmen, claimed the hour for "grinding money" in addition to an hour's notice.—Mr. De Rutzen said if the object of the gentleman who drafted the rules was to give as much trouble as possible in their interpretation he had succeeded admirably. With the advantage of having tried several of these cases, and of having heard a great deal of evidence as to trade custom, he (the magistrate) was of opinion that the real intention of the rule in dispute was to give men situated as the complainants were an hour's grinding-money, in addition to the hour's notice to which they were clearly entitled. Judgement was therefore in favour of the workmen. Complainants asked for costs.—Mr. De Rutzen said he should not give any costs beyond the costs of the summonses, because the rule was open to argument.

WATER SUPPLY AND SANITARY MATTERS.

ABINGDON SEWERAGE.—A portion of this work, under Mr. G. Winship, surveyor to the borough, has just been carried out. Owing to the nature of the ground, the work was attended with some difficulty, the subsoil water (influenced by the level of the river Thames) standing during the summer 5ft. and upwards above the invert of the sewer, and the soil for a considerable length being of running sand. Stoneware pipes, with Doulton's self-adjusting joint, were adopted, and a very satisfactory result has been obtained.

EDINBURGH AND LEITH.—An important stage in the Water of Leith sewerage and purification scheme

was reached on Monday, when the sewer was joined up in the Blandfield Tunnel, Bonnington. The pipe is now completed from Balerno to the sea. The sewer begins at Balerno with an 18in. pipe, and increases in size to 4ft. 6in., and eventually to a tunnel 7ft. 6in. by 8ft. 6in. Thence the sewage is taken by iron pipes, 5ft. in diameter, to the sea at the Black Rocks. The tanks, settling ponds, and drains in connection with the mills and works in the Water of Leith valley are now well advanced, and the whole scheme will be in operation in the course of the next six months. In the mean time, the effect of the work accomplished on Monday will be that the sewage can now be taken direct to the sea. The Parliamentary estimates for the work amounted to £145,000; but these have been greatly exceeded, chiefly on account of the unexpected increase on compensation claims. The borrowing powers of £200,000 which the Commissioners possess are now all but exhausted, and a Bill is being promoted asking for additional borrowing powers to the extent of £75,000.

WORCESTER.—At the Guildhall, Worcester, Colonel Ducat, R.E., an inspector of the Local Government Board, held an inquiry with reference to the application of the Worcester city council for sanction to borrow £78,000 for the purpose of constructing works for sewage disposal upon land in Bromwich-lane which the city council have agreed to purchase from Earl Beauchamp. By the Worcester Extension Act of 1885 the city was placed under the liability to carry out a scheme of sewage disposal within a limited period. The corporation has only just paid off a loan for large sewerage works which Mr. Hawkesley carried out in 1886, and considerable opposition has been raised to the various schemes recommended. The corporation has approved of the present proposal by 35 votes to 2. Mr. T. Hawkesley, the consulting engineer, said the site was very suitable. The present population was 40,000, and he proposed to provide for 50,000. The annual cost of the works would be £7,000. Mr. F. Candy, C.E., an expert, Major Fosbery, of Warwick, Mr. Mellis, C.E., and Mr. Purchas, Worcester, gave evidence in support of the proposal.

CHIPS.

At a preliminary meeting, held on Wednesday, it was resolved to form a committee for the promotion of a memorial to commemorate the services of the late Sir Richard Owen to science. It is suggested that the memorial should be in the form of a marble statue, to be placed in the hall of the Natural History Museum at South Kensington.

A serious fire occurred on Wednesday night in St. James's-road, Bermondsey, a large three-story building, used as a wholesale cabinet-makers' shop, being completely gutted, while considerable damage was done to adjacent property.

Mr. Harry Hems gave his 24th annual party to aged people of the city at his Ecclesiastical Art Studios at Exeter on St. Stephen's day, feasting on Christmas fare 67 old citizens and their wives. Among the guests present were the bishop of the diocese and the mayor of the city.

Mr. J. W. Start, F.S.I., of Cups Chambers, Colchester, has been favoured with instructions to prepare plans for a village club at Lenden, Colchester, for Captain Naylor-Leyland, M.P.

On Thursday, Dec. 22, an inquiry was held at the town hall, Haverhill, by Col. J. O. Halstead, an inspector of the Local Government Board, who attended for the purpose of learning any objections to the local board of Haverhill borrowing £8,400 for works of water supply and £1,800 for street improvements. No opposition was offered to the proposals of the board.

Messrs. Bailey Denton, Son, and North, MM. Inst. C.E., have been instructed by the guardians of the Ware Union to prepare plans and specifications for the water supply of Broxbourne and Wormley, Herts. The supply of water to be obtained from the mains of the Cheshunt Local Board, and a storage reservoir for the use of combined district is to be built in the parish of Broxbourne. A scheme of public water supply will prove of great benefit to this very favourite residential neighbourhood.

Mr. Tulloch, an inspector to the Local Government Board, held an inquiry at the Sailors' Institute, Goole, on Friday, relative to an application by the Goole local board for power to borrow £9,245 for certain works, including £4,000 for the purchase of a site for a market hall.

The Runcorn rural sanitary authority have adopted plans by Mr. Percy Sulcock, C.E., for the extension of the sewage works, at an estimated cost of £1,500.

In the case of the bankruptcy of William Inkpen and Walter Inkpen (trading as William Inkpen and Son), Sturminster Newton, Dorsetshire, builders and contractors, the discharge from bankruptcy has been suspended for two years ending Nov. 15, 1894.

Our Office Table.

"MINIATURES" formed the subject of a lecture delivered by Mr. J. W. Bradley on Friday evening before the Birmingham and Midland Institute. He dealt with the kind of painting employed in the ages before the 16th century, and not the modern portrait painters—of the rules and canons under which miniatures were produced, and the necessity for monastic interference in these matters. Mr. Bradley defined illumination, and distinguished it from miniature, and alluded to the different styles from the Byzantine to the English period. He sketched the gradual development of the art of historic miniature, its qualities and limits, and mentioned instances of the cost of illuminated books in the Middle Ages. Thus a Bible belonging to King John of France, which contained over five thousand miniatures in one volume, and nearly five thousand in another, cost 432,000f., or £4,480, independently of vellum, penmanship, and binding. As to how they knew who executed miniatures that were not signed, he said that from the end of the 6th to the end of the 12th century the work might be often identified from a little attention and comparison of the dates in the obituaries of the monasteries. Many of the guild books in existence also formed the means of identifying the work. After the 13th century municipalities and towns and boards of works of cathedrals kept private reporters and books, as also did many distinguished personages. The chief productions in the earliest times were Bibles, sacramentaries, and psalters. After the 12th century the books included sermons, homilies, law treatises, and grammars; the 13th century encyclopedias, romances, and poems; the 14th more Bibles, law books, and romances; and in the 15th century they had everything hitherto produced, with the addition of lay service books, which became fashionable at the beginning of that century for presentation purposes. He spoke, in conclusion, of the four or five great styles in our libraries, and of the names of the miniaturists.

The Manchester Council for the Registration of Plumbers (secretary, Mr. Fred Scott, 44, John Dalton-street) have arranged for a prize essay competition. Prizes of £3 3s. and £1 1s. will be given for the best essays on "Roof-work and down-spouts" (open to registered operative plumbers only), and others of similar amount for the best two essays on "The best system of hot-water circulation for a house of £50 rental, and the best suggestions for supplying hot water to a row of cottages of, say, £15 each." These essays are to deal with the best means of preventing freezing of pipes, cylinders, and cisterns, and the prevention of kitchen-boiler explosions. They will be open to registered operative plumbers under 25 years of age only. Prizes are also offered for the best two essays on "Common defects in plumbers' work, and their remedy." These are open to all plumbers—masters or operatives, registered or not. The essays must be sent in before January 31.

On January 2nd the New York Architectural League will hold its exhibition, and, as formerly, completed work, such as carving in stone and wood, wrought-iron work, mosaic, furniture, and glass, will be shown, besides the architectural drawings and designs forming the bulk of the exhibition. Designers of all schools are admitted, provided their work is good; and exhibits are collected by the promoters of the exhibition from all parts by authorised agents, and prizes are given. The result is the exhibition pays, as the exhibitors are liberally treated.

MEETING FOR THE ENSUING WEEK.

THURSDAY.—Dundee Institute of Architecture. "Curiosities of Architecture in Dundee," by A. H. Miller, F.S.A. Scot., Dundee. 8 p.m.

Holloway's Pills.—For curing diseases of the throat, windpipe, and chest, these Pills have pre-eminently established a world-wide fame, and in complaints of the stomach, liver, and kidneys they are equally efficacious. They are composed of rare balsams, without a single grain of mercury or any other deleterious substance.

BILLS OF QUANTITIES & PLANS.

T. PETTITT and CO. Lithograph Bills of Quantities with the greatest expedition. Accurately copied from the draft in clear hand. Orders from the country returned by evening mail on the same day. Terms on application. Also Plans of Building Estates and General Plan work at very reduced prices.—T. PETTITT and CO., Lithographers, 28, Fitch-street, Soho, London, W. Established 50 years.

Trade News.

WAGES MOVEMENTS.

MIDDLESEX COUNTY COUNCIL AND THE STANDARD WAGE.—Mr. W. Barnes, chairman of the Building Trades Federation, and Mr. J. Rogers have waited upon the chairman of the visiting committee of the Middlesex County Council with regard to the strike at the Middlesex County Asylum at Upper Tooting. The question was discussed, and the committee decided to put all the men engaged at the asylum upon a permanent wage, which would not be less than the current rate for the London district, but which in some cases would exceed it.

KIRKCALDY, N.B.—The master joiners have intimated a reduction of 1d. per hour to take effect from Monday next. The workmen at a meeting held on Friday strongly condemned the action of the masters in making the reduction, considering that the state of trade did not warrant it, and no other town in Scotland had taken such a step. It was agreed, however, to accept the reduction under protest, but to take the earliest opportunity to recover the reduction.

BRICKLAYERS' STRIKE COMMITTEE.—The Central Strike Committee of the Operative Bricklayers' Society have issued a report of their work. The committee were appointed in March last by the Bricklayers' Society to obtain certain advances of wages, and reduction of hours for their members. After preliminary negotiations with the Master Builders' Association, a conference was arranged between all sections of the building trades and the employers. This delay was not pleasing to certain members of the union, and some branches threatened to strike on June 1, but wiser councils prevailed, and on June 10 last the delegates from the Bricklayers', Masons', Plasterers', Carpenters', Painters', Smiths', Fitters', Navvies' and General Labourers' Unions met the Master Builders' Association. The result, as is well known, was a great victory for the men. An agreement was drawn up, which, with one or two small exceptions, has been acted upon throughout the London district. The total cost of the whole movement, including strike pay, picket pay, printing, postage, salaries, and travelling expenses, amounts to £372 18s. 11d., or an average 1s. 3d. per member for the London district. The advance in wages to the London bricklayers alone means £28,116 per annum, besides that which has been obtained by the other trades.

A high-level bridge across the Thames, between Ratcliff and Rotherhithe, is proposed by Max am Ende as being less expensive than the steam ferry projected by the London County Council.

The four-light window over the entrance to the library, on the south-east side of the chancel of Manchester Cathedral, has this week been filled in with stained glass, as a memorial. The window has been executed by Messrs. Heaton, Butler, and Bayne, of London.

The Leeds corporation have accepted a tender for the erection of mortuary chapels at Woodhouse Hill Cemetery, Hunslet, at a cost of £478. The mortuary chapels will form an extension at each end of the present building. The corporation have under consideration a proposal for the acquisition of a site for a cemetery for the district of North Leeds.

CRAIGLEITH STONE.

For STAIRCASES, STEPS, & LANDINGS. VERY HARD, and NEVER WEARS SLIPPERY.

Apply to **J. & A. CREW,** Cumberland Market, London, N.W.

Messrs. CREW have a Large Stock on their Wharves for Selection Telegram—"CRAIGLEITH, LONDON."

DOULTING FREESTONE.

THE CHELYNCH STONE—The Stone from these Quarries is known as the "Weather Bed," and is of a very crystalline nature, and undoubtedly one of the most durable Stones in England.

THE BRAMBLE DITCH STONE is of the same crystalline nature as the Chelynch Stone, but finer in texture and more suitable for fine moulded work.

Prices, and every information given, on application to CHARLES TRASK and SONS, Doulting, Shepton Mallet, Somerset. London Agent:—Mr. E. A. WILLIAMS, 16, Craven-street, Strand, W.
